ESSENTIAL DIMENSION, SPINOR GROUPS, AND QUADRATIC FORMS

PATRICK BROSNAN†, ZINOVY REICHSTEIN†, AND ANGELO VISTOLI‡

Abstract. We prove that the essential dimension of the spinor group Spin grows exponentially with \( n \) and use this result to show that quadratic forms with trivial discriminant and Hasse-Witt invariant are more complex, in high dimensions, than previously expected.

1. Introduction

Let \( K \) be a field of characteristic different from 2 containing a square root of \(-1\), \( W(K) \) be the Witt ring of \( K \) and \( I(K) \) be the ideal of classes of even-dimensional forms in \( W(K) \); cf. [Lam73]. By abuse of notation, we will write \( q \in I^a(K) \) if the Witt class on the non-degenerate quadratic form \( q \) defined over \( K \) lies in \( I^a(K) \). It is well known that every \( q \in I^a(K) \) can be expressed as a sum of the Witt classes of \( a \)-fold Pfister forms defined over \( K \); see, e.g., [Lam73, Proposition II.1.2]. If \( \dim(q) = n \), it is natural to ask how many Pfister forms are needed. When \( a = 1 \) or 2, it is easy to see that \( n \) Pfister forms always suffice; see Proposition [18]. In this paper we will prove the following result, which shows that the situation is quite different when \( a = 3 \).

Theorem 1. Let \( k \) be a field of characteristic different from 2 and \( n \geq 2 \) be an even integer. Then there is a field extension \( K/k \) and an \( n \)-dimensional quadratic form \( q \in I^3(K) \) with the following property: for any finite field extension \( L/K \) of odd degree \( q_L \) is not Witt equivalent to the sum of fewer than

\[
\frac{2^{(n+4)/4} - n - 2}{7}
\]

3-fold Pfister forms over \( L \).

Our proof of Theorem [4] is based on the new results on the essential dimension of the spinor groups Spin, in Section [4], which are of independent interest.

Acknowledgements. We would like to thank the Banff International Research Station in Banff, Alberta (BIRS) for providing the inspiring meeting place where this work was started. We are grateful to A. Merkurjev and B. Totaro for bringing the problem of computing the Pfister numbers $Pf_k(a, n)$ to our attention and for contributing Proposition 19. We also thank N. Fakhruddin for helpful correspondence.

2. Essential dimension

Let $k$ be a field. We will write $\text{Fields}_k$ for the category of field extensions $K/k$. Let $F : \text{Fields}_k \to \text{Sets}$ be a covariant functor.

Let $L/k$ be a field extension. We will say that $a \in F(L)$ descends to an intermediate field $k \subseteq K \subseteq L$ if $a$ is in the image of the induced map $F(K) \to F(L)$.

The essential dimension $\text{ed}(a)$ of $a \in F(L)$ is the minimum of the transcendence degrees $\text{tr} \deg_k K$ taken over all fields $k \subseteq K \subseteq L$ such that $a$ descends to $K$.

The essential dimension $\text{ed}(a; p)$ of $a$ at a prime integer $p$ is the minimum of $\text{ed}(a_{L'})$ taken over all finite field extensions $L'/L$ such that the degree $[L' : L]$ is prime to $p$.

The essential dimension $\text{ed}(F)$ of the functor $F$ (respectively, the essential dimension $\text{ed}(F; p)$ of $F$ at a prime $p$) is the supremum of $\text{ed}(a)$ (respectively, of $\text{ed}(a; p)$) taken over all $a \in F(L)$ with $L$ in $\text{Fields}_k$.

Of particular interest to us will be the Galois cohomology functors, $F_G$ given by $K \rightsquigarrow H^1(K, G)$, where $G$ is an algebraic group over $k$. Here, as usual, $H^1(K, G)$ denotes the set of isomorphism classes of $G$-torsors over $\text{Spec}(K)$, in the fppf topology. The essential dimension of this functor is a numerical invariant of $G$, which, roughly speaking, measures the complexity of $G$-torsors over fields. We write $\text{ed} G$ for $\text{ed} F_G$ and $\text{ed}(G; p)$ for $\text{ed}(F_G; p)$.

Essential dimension was originally introduced in this context; see [BR97, Rei00, RY00]. The above definition of essential dimension for a general functor $F$ is due to A. Merkurjev; see [BF03].

Recall that an action of an algebraic group $G$ on an algebraic variety $k$-variety $X$ is called “generically free” if $X$ has a dense open subset $U$ such that $\text{Stab}_G(x) = \{1\}$ for every $x \in U(F)$.

Lemma 2. Let $G$ be a linear algebraic group and $V$ be a generically free linear representation of $G$. Then $\text{ed}(G) \leq \dim(V) - \dim(G)$.

Proof. See [Rei00] Theorem 3.4] (which is stated in characteristic 0 only, but the proof goes through in any characteristic) or [BF03] Lemma 4.11].

Lemma 3. If $G$ is an algebraic group and $H$ is a closed subgroup of codimension $e$ then

(a) $\text{ed}(G) \geq \text{ed}(H) - e$, and

(b) $\text{ed}(G; p) \geq \text{ed}(H; p) - e$ for any prime integer $p$. 
Proof. Part (a) is \cite[Theorem 6.19]{BF03}. Both (a) and (b) follow directly from \cite[Principle 2.10]{Bro07}.

If \(G\) is a finite abstract group, we will write \(ed_k G\) (respectively, \(ed_k(G; p)\)) for the essential dimension (respectively, for the essential dimension at \(p\)) of the constant group \(G_k\) over the field \(k\). Let \(C(G)\) denote the center of \(G\).

**Theorem 4.** Let \(G\) be a \(p\)-group whose commutator \([G, G]\) is central and cyclic. Then \(ed_k(G; p) = ed_k G = \sqrt{|G/C(G)|} + \text{rank } C(G) - 1\) for any base field \(k\) of characteristic \(\neq p\) containing a primitive root of unity of degree equal to the exponent of \(G\).

Note that with the above hypotheses, \(|G/C(G)|\) is a complete square. Theorem 4 was originally proved in \cite{BRV07} as a consequence of our study of essential dimension of gerbes banded by \(\mu_{p^n}\). Karpenko and Merkurjev \cite{KM07} have subsequently refined our arguments to show that the essential dimension of any finite \(p\)-group over any field \(k\) containing a primitive \(p\)-th root of unity is the minimal dimension of a faithful linear \(G\)-representation defined over \(k\). Using \cite[Remark 4.7]{KM07} Theorem 4 is easily seen to be a special case of their formula. For this reason we omit the proof here.

3. **Essential dimension of Spin groups**

As usual, we will write \(\langle a_1, \ldots, a_n \rangle\) for the quadratic form \(q\) of rank \(n\) given by \(q(x_1, \ldots, x_n) = \sum_{i=1}^{n} a_i x_i^2\). Let
\[
 h = \langle 1, -1 \rangle
\]
denote the 2-dimensional hyperbolic quadratic form over \(k\). For each \(n \geq 0\) we define the \(n\)-dimensional split form \(q_n^{\text{split}}\) defined over \(k\) as follows:
\[
 q_n^{\text{split}} = \begin{cases} 
 h \oplus n/2 & \text{if } n \text{ is even}, \\
 h \oplus (n-1)/2 \oplus \langle 1 \rangle & \text{if } n \text{ is odd}.
\end{cases}
\]

Let \(\text{Spin}_n \overset{\text{def}}{=} \text{Spin}(q_n^{\text{split}})\) be the split form of the spin group. We will also denote the split forms of the orthogonal and special orthogonal groups by \(\text{O}_n \overset{\text{def}}{=} O(q_n^{\text{split}})\) and \(\text{SO}_n \overset{\text{def}}{=} \text{SO}(q_n^{\text{split}})\) respectively. The main result of this section is the following theorem.

**Theorem 6.** (a) Let \(k\) be a field of characteristic \(\neq 2\) and \(n \geq 15\) be an integer.
\[
 ed(\text{Spin}_n; 2) \geq \begin{cases} 
 2^{(n-1)/2} - \frac{n(n-1)}{2} & \text{if } n \text{ is odd}, \\
 2^{(n-2)/2} - \frac{n(n-1)}{2} & \text{if } n \equiv 2 \pmod{4}, \\
 2^{(n-2)/2} - \frac{n(n-1)}{2} + 1 & \text{if } n \equiv 0 \pmod{4}.
\end{cases}
\]
(b) Moreover if \(\text{char}(k) = 0\) then
\[
 ed(\text{Spin}_n) = ed(\text{Spin}_n; 2) = 2^{(n-1)/2} - \frac{n(n-1)}{2} \quad \text{if } n \text{ is odd},
\]
\[
 ed(\text{Spin}_n) = ed(\text{Spin}_n; 2) = 2^{(n-2)/2} - \frac{n(n-1)}{2} \quad \text{if } n \equiv 2 \pmod{4}, \text{ and}
\]
ed(\text{Spin}_n; 2) \leq \text{ed}(\text{Spin}_n) \leq 2^{(n-2)/2} - \frac{n(n-1)}{2} + n, \text{ if } n \equiv 0 \pmod{4}.

Note that while the proof of part (a) below goes through for any \( n \geq 3 \), our lower bounds become negative (and thus vacuous) for \( n \leq 14 \).

**Proof.** (a) Since replacing \( n \) by a larger field \( k' \) can only decrease the value of \( \text{ed}(\text{Spin}_n; 2) \), we may assume without loss of generality that \( \sqrt{-1} \in k \). The \( n \)-dimensional split quadratic form \( q_n^{\text{split}} \) is then \( k \)-isomorphic to \( (7) q(x_1, \ldots, x_n) = -(x_1^2 + \cdots + x_n^2) \).

Thus in order to prove the lower bounds of part (a), it suffices to show that

\[
\text{ed}(\text{Spin}_n; 2) \geq \text{ed}(G_n; 2) - \frac{n(n-1)}{2}.
\]

Thus in order to prove the lower bounds of part (a), it suffices to show that

\[
(8) \quad \text{ed}(G_n; 2) = \text{ed}(G_n) = \begin{cases} 2^{(n-1)/2}, & \text{if } n \text{ is odd,} \\ 2^{(n-2)/2}, & \text{if } n \equiv 2 \pmod{4}, \\ 2^{(n-2)/2} + 1, & \text{if } n \text{ is divisible by 4.} 
\end{cases}
\]

The structure of the finite 2-group \( G_n \) is well understood; see, e.g., [Woo89]. Recall that the Clifford algebra \( A_n \) of the quadratic form \( q \), as in (7), is the algebra given by generators \( e_1, \ldots, e_n \), and relations \( e_i^2 = -1, e_ie_j + e_je_i = 0 \) for all \( i \neq j \). For any \( I \subseteq \{1, \ldots, n\} \) write \( I = \{i_1, \ldots, i_r\} \) with \( i_1 < i_2 < \cdots < i_r \). Set \( e_I \) = \( e_{i_1} \cdots e_{i_r} \). Here \( e_0 = 1 \). The group \( G_n \) consists of the elements of \( A_n \) of the form \( \pm e_I \), where \( I \subseteq \{1, \ldots, n\} \) and the cardinality \( |I| \) of \( I \) is even. The element \(-1\) is central, and the commutator \([e_I, e_J]\) is given by \([e_I, e_J] = (-1)^{|I \cap J|}\). It is clear from this description that \( G_n \) is a 2-group of order \( 2^n \), the commutator subgroup \([G_n, G_n] = \{\pm 1\}\) is cyclic, and the center \( C(G) \) is as follows:

\[
C(G_n) = \begin{cases} \{\pm 1\} \simeq \mathbb{Z}/2\mathbb{Z}, & \text{if } n \text{ is odd,} \\ \{\pm 1, \pm e_{\{1, \ldots, n\}}\} \simeq \mathbb{Z}/4\mathbb{Z}, & \text{if } n \equiv 2 \pmod{4}, \\ \{\pm 1, \pm e_{\{1, \ldots, n\}}\} \simeq \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}, & \text{if } n \text{ is divisible by 4.} 
\end{cases}
\]

Formula (8) now follows from Theorem 4.

(b) Clearly \( \text{ed}(\text{Spin}_n; 2) \leq \text{ed}(\text{Spin}_n) \). Hence, we only need to show that for \( n \geq 15 \)

\[
(9) \quad \text{ed}(\text{Spin}_n) \leq \begin{cases} 2^{(n-1)/2} - \frac{n(n-1)}{2}, & \text{if } n \text{ is odd,} \\ 2^{(n-2)/2} - \frac{n(n-1)}{2}, & \text{if } n \equiv 2 \pmod{4}, \\ 2^{(n-2)/2} - \frac{n(n-1)}{2} + n, & \text{if } n \equiv 0 \pmod{4}.
\end{cases}
\]
In view of Lemma 2 it suffices to show that $\text{Spin}_n$ has a generically free linear representation $V$ of dimension

$$\dim(V) = \begin{cases} 
2^{(n-1)/2}, & \text{if } n \text{ is odd}, \\
2^{(n-2)/2}, & \text{if } n \equiv 2 \pmod{4}, \\
2^{(n-2)/2} + n, & \text{if } n \equiv 0 \pmod{4}.
\end{cases}$$

Our construction of $V$ will be based on the following fact; see [VP89, Theorem 7.11].

**Lemma 11.** The following representations of $\text{Spin}_n$ over a field $k$ of characteristic 0 are generically free:

(i) the spin representation, if $n \geq 15$ is odd,

(ii) either of the two half-spin representation, if $n = 4m + 2$ for some integer $m \geq 4$.

**Proof.** For $n \geq 27$ this follows directly from [AP71, Theorem 1]. For $n$ between 15 and 25 this is proved in [Pop85].

Since the dimension of the spin representation of $\text{Spin}_n$ is $2^{(n-1)/2}$ (for $n$ odd) and the dimension of the half-spin representation is $2^{(n-2)/2}$ (for $n$ even), this completes the proof of part (b) in the cases where $n \geq 15$ is not divisible by 4.

In the case where $n \geq 16$ is divisible by 4, we define $V$ as the sum of the half-spin representation $W$ of $\text{Spin}_n$ and the natural representation $k^n$ of $\text{SO}_n$, which we will view as a $\text{Spin}_n$-representation via the projection $\text{Spin}_n \to \text{SO}_n$. It remains to check that $V = W \times k^n$ is a generically free representation of $\text{Spin}_n$. Indeed, for $a \in k^n$ in general position, $\text{Stab}(a)$ (embedded in $\text{Spin}_n$ in the standard way). Thus it suffices to show that the restriction of $W$ to $\text{Spin}_{n-1}$ is generically free. Since $W$ restricted to $\text{Spin}_{n-1}$ is the spin representation of $\text{Spin}_{n-1}$ (see, e.g., [Ada96, Proposition 4.4]), and $n \geq 16$, this follows from Lemma 11(i).

**Remark 12.** The only time the characteristic 0 assumption is used in part (b) is in the proof of Lemma 11. It is likely that Lemma 11 (and thus Theorem 6(b)) remain true if $\text{char}(k) = p > 0$ but we have not checked this.

If $p \neq 2$ and $\sqrt{-1} \in k$, we have the weaker (but asymptotically equivalent) upper bound $\text{ed}(\text{Spin}_n) \leq \text{ed}(G_n)$, where $\text{ed}(G_n)$ is given by (8). This is a consequence of the fact that every $\text{Spin}_n$-torsor admits reduction of structure to $G_n$, i.e., the natural map $H^1(K, G_n) \to H^1(K, \text{Spin}_n)$ is surjective for every field $K/k$; cf. [BF03, Lemma 1.9].

**Remark 13.** The best previously known lower bounds on $\text{ed}(\text{Spin}_n)$, due of V. Chernousov and J.-P. Serre [CS06], were

$$\text{ed}(\text{Spin}_n; 2) \geq \begin{cases} 
\lfloor n/2 \rfloor + 1, & \text{if } n \geq 7 \text{ and } n \equiv 1, 0 \text{ or } -1 \pmod{8}, \\
\lfloor n/2 \rfloor, & \text{for all other } n \geq 11.
\end{cases}$$
(The first line is due to B. Youssin and the second author in the case that \( \text{char } k = 0 \).) Moreover, in low dimensions, M. Rost \cite{Ros99} computed the following table of exact values:

\[
\begin{array}{cccccccc}
\text{Spin}_3 &=& 0 & \text{Spin}_4 &=& 0 & \text{Spin}_5 &=& 0 & \text{Spin}_6 &=& 0 \\
\text{Spin}_7 &=& 4 & \text{Spin}_8 &=& 5 & \text{Spin}_9 &=& 5 & \text{Spin}_{10} &=& 4 \\
\text{Spin}_{11} &=& 5 & \text{Spin}_{12} &=& 6 & \text{Spin}_{13} &=& 6 & \text{Spin}_{14} &=& 7;
\end{array}
\]

cf. also \cite{Gar}. Taken together these results seemed to suggest that \( \text{ed } \text{Spin}_n \) should be a slowly increasing function of \( n \) and gave no hint of its exponential growth.

**Remark 14.** A. S. Merkurjev (unpublished) recently strengthened our lower bound on \( \text{ed } (\text{Spin}_n; 2) \), in the case where \( n \equiv 0 \pmod{4} \) as follows:

\[
\text{ed } (\text{Spin}_n; 2) \geq 2^{(n-2)/2} - \frac{n(n-1)}{2} + 2^m,
\]

where \( 2^m \) is the highest power of 2 dividing \( n \). If \( n \geq 16 \) is a power of 2 and \( \text{char}(k) = 0 \) this, in combination with the upper bound of Theorem 6(b), yields

\[
\text{ed } (\text{Spin}_n; 2) = \text{ed } (\text{Spin}_n) = 2^{(n-2)/2} - \frac{n(n-1)}{2} + n.
\]

In particular, \( \text{ed } (\text{Spin}_{16}) = 24 \). The first value of \( n \) for which \( \text{ed } (\text{Spin}_n) \) is not known is \( n = 20 \), where \( 326 \leq \text{ed } (\text{Spin}_{20}) \leq 342 \).

**Remark 15.** The same argument can be applied to the half-spin groups yielding

\[
\text{ed } (\text{HSpin}_n; 2) = \text{ed } (\text{HSpin}_n) = 2^{(n-2)/2} - \frac{n(n-1)}{2}
\]

for any integer \( n \geq 20 \) divisible by 4 over any field of characteristic 0. Here, as in Theorem 6, the lower bound

\[
\text{ed } (\text{HSpin}_n; 2) \geq 2^{(n-2)/2} - \frac{n(n-1)}{2}
\]

is valid for over any base field \( k \) of characteristic \( \neq 2 \). The assumptions that \( \text{char}(k) = 0 \) and \( n \geq 20 \) ensure that the half-spin representation of \( \text{HSpin}_n \) is generically free; see \cite[Theorem 7.11]{VP89}.

**Remark 16.** Theorem 6 implies that for large \( n \), \( \text{Spin}_n \) is an example of a split, semisimple, connected linear algebraic group whose essential dimension exceeds its dimension. Previously no examples of this kind were known, even for \( k = \mathbb{C} \).

Note that no complex connected semisimple adjoint group \( G \) can have this property. Indeed, every such \( G \) has a generically free representation \( V = g \times g \), where \( g \) is the adjoint representation of \( G \) on its Lie algebra; cf., e.g., \cite[Lemma 3.3(b)]{Ric88}. Thus \( \text{ed } G \leq \dim(G) \) by Lemma 2.
Remark 17. Since $ed_{SO_n} = n - 1$ for every $n \geq 3$ (cf. [Rei00, Theorem 10.4]), for large $n$, Spin$_n$ is also an example of a split, semisimple, connected linear algebraic group $G$ with a central subgroup $Z$ such that $ed G > ed G/Z$. To the best of our knowledge, this example is new as well.

4. Pfister numbers

Let $K$ be a field of characteristic not equal to 2 and $a \geq 1$ be an integer. We will continue to denote the Witt ring of $K$ by $W(K)$ and its fundamental ideal by $I(K)$. If non-singular quadratic forms $q$ and $q'$ over $K$ are Witt equivalent, we will write $q \sim q'$.

As we mentioned in the introduction, the $a$-fold Pfister forms generate $I^a(K)$ as an abelian group. In other words, every $q \in I^a(K)$ is Witt equivalent to $\sum_{i=1}^r \langle a_i \rangle$, where each $a_i$ is an $a$-fold Pfister form over $K$. We now define the $a$-Pfister number of $q$ to be the smallest possible number $r$ of Pfister forms appearing in any such sum. The $(a, n)$-Pfister number $Pf_k(a, n)$ is the supremum of the $a$-Pfister number of $q$, taken over all field extensions $K/k$ and all $n$-dimensional forms $q \in I^a(K)$.

Proposition 18. Let $k$ be a field of characteristic $\neq 2$ and let $n$ be a positive even integer.

(a) $Pf_k(1, n) \leq n$.

(b) $Pf_k(2, n) \leq n - 2$.

Proof. (a) Immediate from the identity

$$\langle a_1, a_2 \rangle \sim \langle a_1 \rangle - \langle -a_2 \rangle = \langle -a_1 \rangle \geq \langle a_2 \rangle$$

in the Witt ring.

(b) Let $q = \langle a_1, \ldots, a_n \rangle$ be an $n$-dimensional quadratic form over $K$. Recall that $q \in I^2(K)$ iff $n$ is even and $d_\pm(q) = 1$, modulo $(K^*)^2$ [Lam73, Corollary II.2.2]. Here $d_\pm(q)$ is the signed discriminant given by $(-1)^{n(n-1)/2} d(q)$ where $d(q) = \prod_{i=1}^n a_i$ is the discriminant of $q$; cf. [Lam73] p. 38.

To explain how to write $q$ as a sum of $n - 2$ Pfister forms, we will temporarily assume that $\sqrt{-1} \in K$. In this case we may assume that $a_1 \ldots a_n = 1$. Since $\langle a, a \rangle$ is hyperbolic for every $a \in K^*$, we see that $q = \langle a_1, \ldots, a_n \rangle$ is Witt equivalent to

$$\langle a_2, a_1 \rangle \oplus \langle a_3, a_1 a_2 \rangle \oplus \cdots \oplus \langle a_{n-1}, 1, a_1 \ldots a_{n-2} \rangle \ .$$

By inserting appropriate powers of $-1$, we can modify this formula so that it remains valid even if we do not assume that $\sqrt{-1} \in K$, as follows:

$$q = \langle a_1, \ldots, a_n \rangle \sim \sum_{i=2}^n (-1)^i \langle -1 \rangle^{i+1} a_i, (-1)^{i(i-1)/2+1} a_1 \ldots a_{i-1} \rangle \ .$$

We do not have an explicit upper bound on $Pf_k(3, n)$; however, we do know that $Pf_k(3, n)$ is finite for any $k$ and any $n$. To explain this, let us recall that $I^3(K)$ is the set of all classes $q \in W(K)$ such that $q$ has even dimension,
trivial signed discriminant and trivial Hasse-Witt invariant \cite{KMRT98}. The following result was suggested to us by Merkurjev and Totaro.

**Proposition 19.** Let $k$ be a field of characteristic different from 2. Then $\text{Pf}_k(3, n)$ is finite.

**Sketch of proof.** Let $E$ be a versal torsor for $\text{Spin}_n$ over a field extension $L/k$; cf. \cite[Section I.V]{GMS03}. Let $q_L$ be the quadratic form over $L$ corresponding to $E$ under the map $H^1(L, \text{Spin}_n) \to H^1(L, \text{O}_n)$. The 3-Pfister number of $q_L$ is then an upper bound for the 3-Pfister number of any $n$-dimensional form in $I^3$ over any field extension $K/k$.

**Remark 20.** For $a > 3$ the finiteness of $\text{Pf}_k(a, n)$ is an open problem.

5. **Proof of Theorem**

The goal of this section is to prove Theorem stated in the introduction, which says, in particular, that

$$\text{Pf}_k(3, n) \geq \frac{2^{(n+4)/4} - n - 2}{7}$$

for any field $k$ of characteristic different from 2 and any positive even integer $n$. Clearly, replacing $k$ by a larger field $k'$ strengthens the assertion of Theorem. Thus, we may assume without loss of generality that $\sqrt{-1} \in k$. This assumption will be in force for the remainder of this section.

For each extension $K$ of $k$, denote by $T_n(K)$ the image of $H^1(K, \text{Spin}_n)$ in $H^1(K, \text{SO}_n)$. We will view $T_n$ as a functor $\text{Fields}_k \to \text{Sets}$. Note that $T_n(K)$ is the set of isomorphism classes of $n$-dimensional quadratic forms $q \in I^3(K)$.

**Lemma 21.** We have the following inequalities:

(a) $\text{ed} \text{Spin}_n - 1 \leq \text{ed} T_n \leq \text{ed} \text{Spin}_n$,

(b) $\text{ed} (\text{Spin}_n; 2) - 1 \leq \text{ed} (T_n; 2) \leq \text{ed} (\text{Spin}_n; 2)$.

**Proof.** In the language of \cite[Definition 1.12]{BF03}, we have a fibration of functors

$$H^1(\ast, \mu_2) \sim H^1(\ast, \text{Spin}_n) \to T_n(\ast).$$

The first inequality in part (a) follows from \cite[Proposition 1.13]{BF03} and the second from Proposition \cite[Lemma 1.9]{BF03}. The same argument proves part (b). ♣

Let $K/k$ be a field extension. Let $h_K = \langle 1, -1 \rangle$ be the 2-dimensional hyperbolic form over $K$. (Note in Section 3 we wrote $h$ in place of $h_k$; see \cite{5}.) For each $n$-dimensional quadratic form $q \in I^3(K)$, let $\text{ed}_n(q)$ denote the essential dimension of the class of $q$ in $T_n(K)$.

**Lemma 22.** Let $q$ be an $n$-dimensional quadratic form in $I^3(K)$. Then

$$\text{ed}_{n+2s}(h_K^s \oplus q) \geq \text{ed}_n(q) - \frac{s(s + 2n - 1)}{2}$$

for any integer $s \geq 0$. 
Proof. Set \( m \overset{\text{def}}{=} \text{ed}_{n+2s}(h_{K}^{\oplus s} \oplus q) \). By definition, \( h_{K}^{\oplus s} \oplus q \) descends to an intermediate subfield \( k \subset F \subset K \) such that \( \text{tr} \text{deg}_k(F) = m \). In other words, there is an \((n + 2s)\)-dimensional quadratic form \( \tilde{q} \in I^3(F) \) such that \( \tilde{q}_k \) is \( K \)-isomorphic to \( h_{K}^{\oplus s} \oplus q \). Let \( X \) be the Grassmannian of \( s \)-dimensional subspaces of \( F^{n+2s} \) which are totally isotropic with respect to \( \tilde{q} \). The dimension of \( X \) over \( F \) is \( s(s + 2n - 1)/2 \).

The variety \( X \) has a rational point over \( K \); hence there exists an intermediate extension \( F \subseteq E \subseteq K \) such that \( \text{tr} \text{deg}_F(E) \leq s(s + 2n - 1)/2 \), with the property that \( \tilde{q}_E \) has a totally isotropic subspace of dimension \( s \). Then \( \tilde{q}_E \) splits as \( h_{E}^{s} \oplus q' \), where \( q' \in I^3(E) \). By Witt’s Cancellation Theorem, \( q'_K \) is \( K \)-isomorphic to \( q \); hence

\[
\text{ed}_n(q) \leq \text{tr} \text{deg}_k(E) = \text{tr} \text{deg}_k(F) + \text{tr} \text{deg}_F(E) = m + s(s + 2n - 1)/2,
\]

as claimed. \( \square \)

We now proceed with the proof of Theorem 1. For \( n \leq 10 \) the statement of the theorem is vacuous, because \( 2^{(n+1)/4} - n - 2 \geq 0 \). Thus we will assume from now on that \( n \geq 12 \).

Lemma 21 implies, in particular, that \( \text{ed}(T_n; 2) \) is finite. Hence, there exist a field \( K/k \) and an \( n \)-dimensional form \( q \in I^3(K) \) such that \( \text{ed}_n(q) = \text{ed}(T_n; 2) \). We will show that this form has the properties asserted by Theorem 1. In fact, it suffices to prove that if \( q \) is Witt equivalent to

\[
\sum_{i=1}^{r} \langle a_i, b_i, c_i \rangle.
\]

over \( K \) then \( r \geq \frac{2^{(n+4)/4} - n - 2}{7} \). Indeed, \( \text{ed}_n(q_L) = \text{ed}(T_n; 2) \) for any finite odd degree extension \( L/K \). Thus if we can prove the above inequality for \( q \), it will also be valid for \( q_L \).

Let us write a 3-fold Pfister form \( \langle a, b, c \rangle \) as \( \langle a, b, c \rangle = \langle 1 \rangle \oplus \langle a, b, c \rangle_0 \), where

\[
\langle a, b, c \rangle_0 \overset{\text{def}}{=} \langle a_i, b_i, c_i \rangle.
\]

Set

\[
\phi \overset{\text{def}}{=} \begin{cases} 
\sum_{i=1}^{r} \langle a_i, b_i, c_i \rangle_0 & \text{if } r \text{ is even, and} \\
\langle 1 \rangle \oplus \sum_{i=1}^{r} \langle a_i, b_i, c_i \rangle_0 & \text{if } r \text{ is odd.}
\end{cases}
\]

Then \( q \) is Witt equivalent to \( \phi \) over \( K \); in particular, \( \phi \in I^3(K) \). The dimension of \( \phi \) is \( 7r \) or \( 7r + 1 \), depending on the parity of \( r \).

We claim that \( n < 7r \). Indeed, assume the contrary. Then \( \dim(q) \leq \dim(\phi) \), so that \( q \) is isomorphic to a form of type \( h_{K}^{s} \oplus \phi \) over \( K \). Thus

\[
\frac{3n}{7} \geq 3r \geq \text{ed}_n(q) = \text{ed}(T_n; 2) \overset{\text{by Lemma 21}}{\geq} \text{ed}(\text{Spin}_n; 2) - 1.
\]

The resulting inequality fails for every even \( n \geq 12 \) because for such \( n \)

\[
\text{ed}(\text{Spin}_n; 2) \geq n/2;
\]
see Remark 13.

So, we may assume that $7r > n$, i.e., $\phi$ is isomorphic to $h^s \oplus q$ over $K$, for some $s \geq 1$. By comparing dimensions we get the equality $7r = n + 2s$ when $r$ is even, and $7r + 1 = n + 2s$ when $r$ is odd. The essential dimension of the form $\phi$, as an element of $T_{7r}(K)$ or $T_{7r+1}(K)$ is at most $3r$, while Lemma 22 tells us that this essential dimension is at least $\text{ed}(q) - s(s + 2n - 1)/2$.

From this, Lemma 21 and Theorem 6(a) we obtain the following chain of inequalities

$$3r \geq \text{ed}_n(q) - \frac{s(s + 2n - 1)}{2} = \text{ed}(T_n:2) - \frac{s(s + 2n - 1)}{2}$$

(23)

$$\geq \text{ed} \mathbf{Spin}_n - 1 - \frac{s(s + 2n - 1)}{2} \geq 2^{(n-2)/2} - \frac{n(n - 1)}{2} - 1 - \frac{s(s + 2n - 1)}{2}.$$

Now suppose $r$ is even. Substituting $s = (7r - n)/2$ into inequality (23), we obtain

$$49r^2 + (14n + 10)r - 2^{(n+4)/2} - n^2 + 2n - 8 \geq 0.$$

We interpret the left hand side as a quadratic polynomial in $r$. The constant term of this polynomial is negative for all $n \geq 8$; hence this polynomial has one positive real root and one negative real root. Denote the positive root by $r_+$. The above inequality is then equivalent to $r \geq r_+$. By the quadratic formula

$$r_+ = \frac{\sqrt{49 \cdot 2^{(n+4)/2} + 168n - 367} - (7n + 5)}{49} \geq \frac{2^{(n+4)/4} - n - 2}{7}.$$

This completes the proof of Theorem 1 when $r$ is even. If $r$ is odd then substituting $s = (7r + 1 - n)/2$ into (23), we obtain an analogous quadratic inequality whose positive root is

$$r_+ = \frac{\sqrt{49 \cdot 2^{(n+4)/2} + 168n - 199} - (7n + 12)}{49} \geq \frac{2^{(n+4)/4} - n - 2}{7},$$

and Theorem 1 follows. ♠
