Abstract. The Segre-Gimigliano-Harbourne-Hirschowitz Conjecture can be naturally formulated for Hirzebruch surfaces $F_n$. We show that this Conjecture holds for imposed base points of equal multiplicity bounded by 8.

1. Linear systems on Hirzebruch surfaces

Our goal is to prove Conjecture 4 for linear systems on Hirzebruch surfaces with imposed base points of equal multiplicity bounded by 8. This Conjecture, being a natural reformulation of the Segre-Harbourne-Gimigliano-Hirschowitz Conjecture, has been stated in [Laf 02, Conjecture 2.6]. In the same paper it is shown (Theorem 7.1) that this Conjecture holds for systems with imposed base points of equal multiplicity bounded by 3. We will also give another proof of [Laf 02, Proposition 2.7], where the proof contains a serious mistake (for more details see the proof of Proposition 29).

Our method will also work for greater values of multiplicities, but the computational part (realized with the help of computers) becomes very large and time-consuming. But it is possible to carry our computations further to obtain the proof for $m_1 = \ldots = m_r = 9, 10, \ldots$ or to find a counterexample.

The author would like to thank Michał Kapustka and Tomasz Szemberg for valuable discussions.

By $F_n$, $n \geq 0$, we denote the rational ruled surface (called the $n$-th Hirzebruch surface) given by $F_n = \mathbb{P} (\mathcal{O}_1 \oplus \mathcal{O}_{\mathbb{P}^1} (n))$ over the field $\mathbb{K}$ of characteristic 0. The Picard group $\text{Pic} (F_n)$ can be freely generated by the class of a fiber $F_n$ and the class of the section $H_n$ such that $F_n^2 = 0$, $H_n^2 = n$, $F_n \cdot H_n = 1$. The irreducible section with self-intersection $-n$ will be denoted by $\Gamma_n$, we have $\Gamma_n \in |H_n - nF_n|$. The class of $\Gamma_n$ in $\text{Pic} (F_n)$ will also be denoted by $\Gamma_n$. Let $a, b$ be integers. By $L_n(a, b)$ we will denote the complete linear system associated to the line bundle $aF_n + bH_n$.

Lemma 1. If on $F_n$ the class $aF_n + bH_n$ contains an effective divisor then there exists non-negative integers $a', b'$, $q$ ($q > 0$ if and only if $a < 0$) such that the base locus of $|aF_n + bH_n|$ is $q\Gamma_n$ and $aF_n + bH_n$ is linearly equivalent to $q\Gamma_n + a'F_n + b'H_n$. Moreover, we have

$$\dim L_n(a, b) = \frac{(b' + 1)(2a' + 2 + nb')}{2} - 1$$

Proof. For the proof see [Laf 02, Proposition 2.2].

Now we pick $r$ points $p_1, \ldots, p_r \in F_n$ in general position, let $m_1, \ldots, m_r$ be non-negative integers. By $L_n(a, b; m_1, \ldots, m_r)$ we denote the linear system of curves in

1991 Mathematics Subject Classification. 14H50; 13P10.
Keywords: linear systems, fat points, Harbourne-Hirschowitz conjecture, Hirzebruch surface.
If this inequality is strict then the system \(L_n(a, b)\) passing through points \(p_1, \ldots, p_r\) with multiplicities at least \(m_1, \ldots, m_r\), respectively. The points \(p_1, \ldots, p_r\) will be called \textit{imposed base points}. The dimension of this system will be denoted by \(\dim L_n(a, b; m_1, \ldots, m_r)\). Define the virtual dimension

\[
\vdim L_n(a, b; m_1, \ldots, m_r) = \dim L_n(a, b) - \sum_{j=1}^{r} \binom{m_j + 1}{2}
\]

and the expected dimension

\[
\edim L_n(a, b; m_1, \ldots, m_r) = \max\{\vdim L_n(a, b; m_1, \ldots, m_r), -1\}.
\]

We have

\[
\dim L_n(a, b; m_1, \ldots, m_r) \geq \edim L_n(a, b; m_1, \ldots, m_r).
\]

If this inequality is strict then the system \(L_n(a, b; m_1, \ldots, m_r)\) is said to be \textit{special}, \textit{non-special} otherwise. The system of negative dimension will be called \textit{empty}.

A natural question is: when a given system is special, and if there exists a geometric explanation to the non-speciality. This can be done by considering \(-1\)-systems.

To introduce the notion of \(-1\)-system and \(-1\)-speciality define the intersection number of \(L = L_n(a, b; m_1, \ldots, m_r)\) and \(L' = L_n(a; m'_1, \ldots, m'_r)\)

\[
L \cdot L' = (aF_n + bH_n) \cdot (a'F_n + b'H_n) - \sum_{j=1}^{r} m_j m'_j
\]

\[
= ab' + a'b + nb'b' - \sum_{j=1}^{r} m_j m'_j.
\]

Observe that if, for nonempty systems, \(L \cdot L' < 0\) then these systems must have a common component. The intersection number of two systems \(L\) and \(L'\) can also be defined by taking the blow-up \(\pi : S \rightarrow \mathbb{P}_n\) at imposed base points and putting \(L \cdot L' = \pi^*(L) \cdot \pi^*(L')\) on \(S\) (see [Laf 02]).

\textbf{Definition 2.} The system \(E = L_n(a, b; m_1, \ldots, m_r)\), \(a, b \geq 0\), satisfying

\[
\dim E = \vdim E = 0, \quad E \cdot E = -1,
\]

with irreducible member is called \textit{\(-1\)-system}.

\textbf{Procedure 1.} Let \(L = L_n(a, b; m_1, \ldots, m_r)\), consider the following procedure:

\begin{itemize}
  \item Step 1. Put \(M \leftarrow L\).
  \item Step 2. If \(M \cdot \Gamma_n < 0\) then take \(M \leftarrow M - \Gamma_n\) and go back to Step 2.
  \item Step 3. If \(M \cdot E < 0\) for some \(-1\)-system \(E\) then take \(M \leftarrow M - E\) and go back to Step 2.
\end{itemize}

The procedure terminates after a finite number of steps.

\textbf{Definition 3.} If, for \(M\) and \(L\) as above, \(\edim M > \dim L\) then \(L\) will be called \textit{\(-1\)-special}.

Observe that if \(L\) is \(-1\)-special then

\[
\dim L = \dim M \geq \edim M > \dim L,
\]

so \(L\) is special. In [Laf 02, Conjecture 2.6] it is conjectured that

\textbf{Conjecture 4.} The system \(L_n(a, b; m_1, \ldots, m_r)\) is special if and only if it is \(-1\)-special.
The analogous Conjecture for the projective plane was stated by several authors and is known as Segre-Harbourne-Gimigliano-Hirschowitz Conjecture (SHGH for short). More on this Conjecture can be found e.g. in [Cil–Mir 08], some recent results are listed in [Dum 08].

Since we are interested mainly in homogeneous systems, we will use the notation \( m^{\times r} \) for repeated multiplicities.

**Example 5.** Let us consider \( L_6(0, 4; 3^{\times 11}) \). Observe that \( \Gamma_n \in L_n(-n, 1) \). We have
\[
L_6(0, 4; 3^{\times 11}) \cdot L_6(-6, 1) = 0,
\]
so we pass to Step 3 in Procedure 1. For the \(-1\)-system \( E = L_6(2, 1; 1^{\times 11}) \) we have
\[
L_6(0, 4; 3^{\times 11}) \cdot E = 8 + 24 - 33 = -1,
\]
so we must take new system \( L_6(-2, 3; 2^{\times 11}) \). In Procedure 1 Step 2
\[
L_6(-2, 3; 2^{\times 11}) \cdot \Gamma_6 = -2,
\]
hence we take out the \(-n\)-section from the base locus and obtain \( L_6(4, 2; 2^{\times 11}) \), which is equal to \( 2E \). Consequently we have that \( L_6(0, 4; 3^{\times 11}) = \Gamma_6 + 3E \), which is non-empty, and since \( \text{vdim} \ L_6(0, 4; 3^{\times 11}) = -2 \), it is \(-1\)-special.

2. Linear systems over \( \mathbb{P}^2 \)

**Definition 6.** Let \( d, m_1, \ldots, m_r, k_1, \ldots, k_s \) be non-negative integers. Pick a general line \( \ell \subset \mathbb{P}^2 \), pick points \( p_1, \ldots, p_r \) in general position, pick points \( q_1, \ldots, q_s \) respectively. The dimension of this system will be denoted by
\[
\dim L(d; m_1, \ldots, m_r, k_1, \ldots, k_s).
\]
Define the **virtual dimension**
\[
\text{vdim} \ L(d; m_1, \ldots, m_r, k_1, \ldots, k_s) = \left( \frac{d + 2}{2} \right) - 1 - \sum_{j=1}^{r} \left( \frac{m_j + 1}{2} \right) - \sum_{j=1}^{s} \left( \frac{k_j + 1}{2} \right)
\]
and the **expected dimension**
\[
\text{edim} \ L(d; m_1, \ldots, m_r, k_1, \ldots, k_s) = \max \{ \text{vdim} \ L(d; m_1, \ldots, m_r, k_1, \ldots, k_s), -1 \}.
\]
We have
\[
\dim L(d; m_1, \ldots, m_r, k_1, \ldots, k_s) \geq \text{edim} \ L(d; m_1, \ldots, m_r, k_1, \ldots, k_s).
\]
If this inequality is strict then the system \( L(d; m_1, \ldots, m_r, k_1, \ldots, k_s) \) is said to be **special**, **non-special** otherwise. We also have the **intersection number**
\[
L(d; m_1, \ldots, m_r, k_1, \ldots, k_s) \cdot L(d'; m'_1, \ldots, m'_r, k'_1, \ldots, k'_s)
\]
\[
= dd' - \sum_{j=1}^{r} m_j m'_j - \sum_{j=1}^{s} k_j k'_j.
\]
Again, we define \(-1\)-system and \(-1\)-speciality.

**Definition 7.** The system \( E = L(d; m_1, \ldots, m_r, k_1, \ldots, k_s) \) satisfying
\[
\dim E = \text{vdim} E = 0, \quad E \cdot E = -1,
\]
with irreducible member is called \(-1\)-**system**.
Procedure 2. Let $L = \mathcal{L}(d; m_1, \ldots, m_r, k_1, \ldots, k_s)$, consider the following procedure:

- Step 1. Put $M \leftarrow L$.
- Step 2. If $M \cdot \mathcal{L}(1; 1^{x}) < 0$ then take $M \leftarrow M - \mathcal{L}(1; 1^{x})$ and go back to Step 2.
- Step 3. If $M \cdot E < 0$ for some planar $-1$-system $E$ then take $M \leftarrow M - E$ and go back to Step 2.

Step 2 should be understood as follows: for $M = \mathcal{L}(d'; m'_1, \ldots, m'_r, k'_1, \ldots, k'_s)$ we have

$$M \cdot \mathcal{L}(1; 1^{x}) = d - \sum_{j=1}^{s} k_j$$

and if this number is negative then the line $\ell$ lies in the base locus of $M$ and can be taken out as follows:

$$M - \mathcal{L}(1; 1^{x}) = \mathcal{L}(d - 1; m_1, \ldots, m_r, k_1 - 1, \ldots, k_s - 1).$$

Definition 8. If, after Procedure 2 terminates, $\text{edim} M > \text{edim} L$ then $L$ will be called $-1$-special.

Example 9. Let us consider $L = \mathcal{L}(28; 24, 3^{x11}, 3^{x7})$. In the next section we will show that $\dim L = \text{dim} \mathcal{L}(0; 4, 3^{x11})$ and $L$ is $-1$-special (resp. special) if and only if $\mathcal{L}(0; 4, 3^{x11})$ is $-1$-special (resp. special). We have $L \cdot E = -1$ for $E = \mathcal{L}(9; 8, 1^{x11}, 1^{x7})$. The residual system $L - E = \mathcal{L}(19; 16, 2^{x11}, 3^{x7})$ has the line in the base locus. Continuing this way we will have $L = \mathcal{L}(1; 1^{x7}) + 3E$, and since $E$ is a $-1$-system, $L$ is $-1$-special.

Remark 10. The original SHGH Conjecture states that for a plane system with imposed base points in general position the speciality is equivalent to the $-1$-speciality. For a system with collinear imposed base points it is natural to extend the definition of the $-1$-speciality as above, which should be called the negative speciality, since the self-intersection of the line passing through $s$ imposed base points is equal to $1 - s$.

We will often consider plane systems and systems on Hirzebruch surfaces. Therefore, we will consequently use the notation: $\mathcal{L}$ without number denotes always the system on $\mathbb{P}^2$, while $\mathcal{L}_n$ the system on $\mathbb{F}_n$.

Proposition 11. Let $d, m_1, \ldots, m_r, k_1, \ldots, k_s$ be non-negative integers.

- Let $k = d - m_1 - m_2 - m_3$, let $m_j^* = \max \{m_j + k, 0\}$ for $j = 1, 2, 3$. Then

$$\dim \mathcal{L}(d; m_1, \ldots, m_r) = \dim \mathcal{L}(d + k; m_1^*, m_2^*, m_3^*, m_4, \ldots, m_r).$$

- Let $k = d - m_1 - m_2 - k_1$, let $m_1^* = \max \{m_1 + k, 0\}$, $m_2^* = \max \{m_2 + k, 0\}$, $k_1^* = \max \{k_1 + k, 0\}$. Then

$$\dim \mathcal{L}(d; m_1, \ldots, m_r, k_1, \ldots, k_s) = \dim \mathcal{L}(d + k; m_1^*, m_2^*, m_3, \ldots, m_r, k_1^*, k_2, \ldots, k_s).$$

Moreover, let $L$ denote the original system and $L^*$ the system after transformation. Then either $\text{edim} L = \text{edim} L^*$ or $\text{edim} L^* > \text{edim} L$ and $L$ is $-1$-special.

Proof. Let $L = \mathcal{L}(d; m_1, \ldots, m_r)$, let $L^* = \mathcal{L}(d + k; m_1^*, m_2^*, m_3^*, m_4, \ldots, m_r)$. To show the first equality we must check if $\mathcal{L}(1; 1, 1, 0)$, $\mathcal{L}(1; 1, 0, 1)$ or $\mathcal{L}(1; 0, 1, 1)$ are in the base locus of $L$ and write

$$L = q_1 \mathcal{L}(1; 1, 1, 0) + q_2 \mathcal{L}(1; 1, 0, 1) + q_3 \mathcal{L}(1; 0, 1, 1) + \tilde{L}.$$
for the system \( \tilde{L} \) without these lines in the base locus. It follows that \( \dim L = \dim \tilde{L} \) and if \( \edim \tilde{L} > \edim L \) then \( L \) is \(-1\)-special. To complete the proof observe that applying the standard birational transformation (so called Cremona transformation) based on points \( p_1, p_2, p_3 \) to \( \tilde{L} \) we obtain the system \( L^* \). By a simple calculation we can show that \( \edim \tilde{L} = \edim L^* \).

To see the second equality observe that \( \mathcal{L}(1;1,0,0) \) is invariant under Cremona transformation, so the line passing through exactly one of the three points will be preserved.

Remark 12. We can apply the above to any three multiplicities, since we can permute imposed points.

Example 13. Let us again (see Example [1]) consider \( L = \mathcal{L}(28; 24,3 \times 11,4 \times 7) \). This time we are only interested in showing that \( L \) is non-empty. We can make Cremona transformation based on points with multiplicity 24, 3 and 4 to obtain \( \mathcal{L}(25; 21,3 \times 10,3 \times 6,1) \). We can repeat this 6 more times, which leads us to a system \( \mathcal{L}(7; 3,3 \times 4,1 \times 7) \). If \( \mathcal{L}(6;3 \times 5) \) is non-empty then \( L \) will also be non-empty. On one hand \( \vdim \mathcal{L}(6;3 \times 5) = -3 \), but on the other hand, applying Cremona, we have that \( \dim \mathcal{L}(6;3 \times 5) = \dim \mathcal{L}(3;3,3) = 0 \).

3. FROM HIRZEBRUCH SURFACE TO \( \mathbb{P}^2 \)

Proposition 14. Let \( n \geq 0 \). For any non-negative integers \( a, b, a', b', m_1, \ldots, m_r, m'_1, \ldots, m'_r \) we have

\[
\dim \mathcal{L}_n(a, b; m_1, \ldots, m_r) = \dim \mathcal{L}(a + (n+1)b; a + nb, m_1, \ldots, m_r, \frac{b^{n+1}}{n+1}),
\]

\[
\vdim \mathcal{L}_n(a, b; m_1, \ldots, m_r) = \vdim \mathcal{L}(a + (n+1)b; a + nb, m_1, \ldots, m_r, \frac{b^{n+1}}{n+1}),
\]

\[
\mathcal{L}_n(a, b; m_1, \ldots, m_r) \cdot \mathcal{L}_n(a', b'; m'_1, \ldots, m'_r)
\]

\[
\cdot \mathcal{L}(a + (n+1)b; a + nb, m_1, \ldots, m_r, \frac{b^{n+1}}{n+1})
\]

Proof. We will use ~ for linear equivalence of divisors. By a straightforward calculation we show the above for the virtual dimension and the intersection number.

Let \( L = \mathcal{L}_n(a, b; m_1, \ldots, m_r) \). For \( n \geq 2 \) consider the blow-up \( \pi_1 : X \rightarrow \mathbb{F}_n \) of a point \( p \) on a fiber \( F_p, p \notin \Gamma_n \). We can also assume that there are no imposed base point on \( F_p \). Let \( \tilde{E} \) be the exceptional divisor of \( \pi_1 \), let \( \pi_1^*(F_p) = \tilde{F}_p + E, \pi_1^*(\Gamma_n) = \tilde{\Gamma} \). Now blow down \( \tilde{F}_p \) (which has self-intersection equal to \(-1\)) with \( \pi_2 : X \rightarrow \mathbb{F}_{n-1} \) (see Figure [1]), let \( q = \pi_2(\tilde{F}_p) \), let \( F_q \) be the fiber on \( \mathbb{F}_{n-1} \) passing through \( q \). The above is often called an elementary transformation. Let \( F \) denote the class of \( \tilde{F}_p \) in \( \text{Pic}(X) \), we will denote the classes of \( \tilde{\Gamma} \) and \( E \) by \( \Gamma \)

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{example.png}
\caption{Elementary transformation between \( \mathbb{F}_n \) and \( \mathbb{F}_{n-1} \)}
\end{figure}

\[F \]
and $E$, respectively. We have $\pi_2^*(F_n) \sim F + E$, $\pi_2^*(\Gamma_{n-1}) = \Gamma + F$. Moreover, $\pi_1^*(H_n) \sim \pi_1^*(\Gamma_{n} + nF_n) \sim \Gamma + nF + nE$, $\pi_2^*(H_{n-1}) \sim \pi_2^*(\Gamma_{n-1} + (n-1)F_{n-1}) = \Gamma + nF + (n-1)E$. The strict transform of the class of a curve in $\mathcal{L}_n(a, b)$ is

$$a \pi_1^*(F_n) + b \pi_1^*(H_n) \sim a(F + E) + b \Gamma + nbF + nbE$$

$$\sim b \Gamma + nbF + b(n - 1)E + (a + b)(F + E) - bF$$

$$\sim (a + b)\pi_2^*(F_{n-1}) + b\pi_2^*(H_{n-1}) - bF.$$

After blowing a curve from $\mathcal{L}_n(a, b)$ up by $\pi_1$ and blowing down by $\pi_2$ we obtain the curve belonging to $\mathcal{L}_{n-1}(a + b, b; b)$, and the point with multiplicity $b$ lies on $\Gamma_{n-1}$. Since $E$ does not belong to the base locus of $\pi_1^*(aF_n + bH_n)$, and $\tilde{F}_p$ belongs to the base locus exactly $b$ times, from Leray spectral sequence we have

$$\dim \mathcal{L}_n(a, b; m_1, \ldots, m_r) = \dim \mathcal{L}_{n-1}(a + b, b; m_1, \ldots, m_r).$$

By repeating the above process we will end up with the system

$$\mathcal{L}_1(a + (n - 1)b; b; b^\times(n-1), m_1, \ldots, m_r),$$

where $n - 1$ imposed base points lies generically on the $-1$-curve $\Gamma_1$.

The surface $F_1$ is isomorphic to $\mathbb{P}^2$ blown up in one point with the exceptional divisor $\Gamma_1$. Take fibers $F_p$ and $F_{p'}$ passing through general points $p$ and $p'$, respectively. Let $H_{pp'} \subset F_1$ be the strict transform of the line (from $\mathbb{P}^2$) joining $p$ and $p'$. Let $\pi_1: X \to F_1$ be the sequence of two blow-ups: of $p$ and $p'$ with exceptional divisors $E$ and $E'$, respectively. Let $\pi_1^*(F_p) = \tilde{F}_p + E$, $\pi_1^*(F_{p'}) = \tilde{F}_{p'} + E'$, $\pi_1^*(\Gamma_1) = \Gamma$, $\pi_1^*(H_{pp'}) = \tilde{H}_{pp'} + E + E'$. Let $F$ (resp. $F'$, $\Gamma$) denote the class of $\tilde{F}_p$ (resp. $\tilde{F}_{p'}$, $\Gamma$) in Pic($X$). We have $\pi_1^*(H_1) \sim E + F \sim \Gamma + E' + F'$. Now take the sequence of three blow-downs $\pi_2: X \to Y$ of $\tilde{F}_p$, $\tilde{F}_{p'}$ and $\tilde{H}_{pp'}$ (see Figure 2).

The above rational transformation $F_1 \to Y$ is nothing else than realizing the Cremona transformation of $\mathbb{P}^2$ by three blow-ups and three blow-downs, but we start with one point blown-up already. It follows that $Y = \mathbb{P}^2$ and $\pi_2^*(\Gamma) \sim \Gamma + F + F'$ for the class of the line $\Gamma = \pi_2(\tilde{\Gamma})$ in $\mathbb{P}^2$. Now, for $\mathcal{L}_1(a, b)$, we have

$$a \pi_1^*(F_1) + b \pi_1^*(H_1) \sim a(F + E) + b(\Gamma + F + F')$$

$$\sim (a + 2b)(\Gamma + F + F') - (a + b)(\Gamma + F' - E) - bF - bF'$$

$$\sim (a + 2b)\pi_2^*(\Gamma) - (a + b)H - bF - bF'.$$

After blowing down we obtain the curve in $\mathcal{L}(a + 2b; a + b, b, b)$. The section $\Gamma_1$ is preserved and mapped to the line $\tilde{\Gamma}$. In consequence we have that, taking $p_1, \ldots, p_r \in F_n$ in general position,

$$\dim \mathcal{L}_n(a, b; m_1, \ldots, m_r) = \dim \mathcal{L}(a + (n + 1)b; a + nb, m_1, \ldots, m_r, b^{n+1}).$$

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{figure2.png}
\caption{Transformation between $F_1$ and $\mathbb{P}^2$}
\end{figure}
For $\mathbb{F}_0 = \mathbb{P}^1 \times \mathbb{P}^1$ the easy proof is left to the reader.

**Remark 15.** Observe that $-1$-systems on $\mathbb{F}_n$ are transformed into $-1$-systems on $\mathbb{P}^2$, since the dimension, virtual dimension, self-intersection and irreducibility is preserved. The section $\Gamma_n$ is mapped into a line which contains $n + 1$ imposed base points with multiplicities $b^{n+1}$. This means, in particular, that the system $\mathcal{L}_n(a, b; m_1, \ldots, m_r)$ is $-1$-special if and only if the planar system

$$\mathcal{L}(a + (n + 1)b; a + nb, m_1, \ldots, m_r, b^{n+1})$$

is $-1$-special (compare Procedures 1 and 2). Additionally we will see that the dimension of each considered $-1$-system $\mathcal{L}(d; m_1, \ldots, m_r, k_1, \ldots, k_s)$ on $\mathbb{P}^2$ will remain 0 after assigning all base points in general position, i.e.

$$\mathcal{L}(d; m_1, \ldots, m_r, k_1, \ldots, k_s)$$

will also be a $-1$-system (see the last section). Therefore we can state the following Conjecture.

**Conjecture 16.**

$$\dim \mathcal{L}(d; m_1, \ldots, m_r, k_1, \ldots, k_s) = \max_{j=0,\ldots,d} \dim \mathcal{L}(d-j; m_1, \ldots, m_r, \max\{k_1-j,0\}, \ldots, \max\{k_s-j,0\}).$$

### 4. Diagrams and reductions

**Definition 17.** Let $a_1, \ldots, a_s$ be non-negative integers. Set $a_j = 0$ for $j > s$ and define the diagram

$$\text{diag}(a_1, \ldots, a_s) = \{(x, y) \in \mathbb{N}^2 : y < a_{x+1}\}.$$ 

We will also write $\lfloor a \rfloor \times p$ for

$$a_1, \ldots, a_p, \underbrace{\ldots}_{p}$$

and $\text{diag}(a_1, \ldots, a_s) + \text{diag}(b_1, \ldots, b_p)$ for $\text{diag}(a_1, \ldots, a_s, b_1, \ldots, b_p)$.

**Example 18.**

Diagram $\text{diag}(1, 2, 3, 4, 3, 2)$

Diagram $\text{diag}(5\times3, 3\times2)$

**Definition 19.** Let $m > 0$, let $a_1, \ldots, a_s$, $b_1, \ldots, b_m$ be non-negative integers, $b_j > 0$ for $j = 1, \ldots, m$. Define $r_1, \ldots, r_m$ inductively (beginning with $r_m$) to be

$$r_j = \begin{cases} b_j & \text{if } b_j < m, \\ \max(\{1, \ldots, m\} \setminus \{r_{j+1}, \ldots, r_m\}) & \text{if } b_j \geq m. \end{cases}$$

If $\{r_1, \ldots, r_m\} = \{1, \ldots, m\}$ then we say that $D = \text{diag}(a_1, \ldots, a_s, b_1, \ldots, b_m)$ is $m$-reducible and define the $m$-reduction of $D$

$$\text{red}_m(D) = \text{diag}(a_1, \ldots, a_s, b_1 - r_1, \ldots, b_m - r_m).$$
Example 20. Let us check if $\text{diag}(6, 6, 6, 3, 1)$ is 4-reducible and find its 4-reduction. We have $(b_1, b_2, b_3, b_4) = (6, 6, 3, 1)$. Beginning with $r_4$ we can see that $b_1 = 1 < 4$, so $r_4 = 1$, the same for $r_3 = b_3 = 3$. Now $b_2 \geq 4$, so we take $\{1, 2, 3, 4\} \setminus \{r_3, r_4\} = \{2, 4\}$ and $p_2 = 4$, which is maximal. The same applies for $r_1 = 2$. We can see that $(r_1, r_2, r_3, r_4) = (2, 4, 3, 1)$, hence $\text{diag}(6, 6, 6, 3, 1)$ is 4-reducible and $\text{red}_4(\text{diag}(6, 6, 6, 3, 1)) = \text{diag}(6, 4, 2)$. We present also another examples of reducing, and two diagrams which are not reducible.

**Definition 21.** Let $D \subset \mathbb{Z}^2$ be a finite set, let $m_1, \ldots, m_r$ be non-negative integers. We will identify points $(\alpha, \beta) \in \mathbb{Z}^2$ with monomials $x^\alpha y^\beta \in \mathbb{K}[x, x^{-1}, y, y^{-1}]$. Take points $p_1, \ldots, p_r$ in general position in $\mathbb{K}^2$ and define the vector space (over $\mathbb{K}$)

$$
\mathcal{L}(D; m_1, \ldots, m_r) = \{ f \in \mathbb{K}[x, x^{-1}, y, y^{-1}] : \text{supp}(f) \subset D, \text{mult}_{p_j} f \geq m_j \text{ for } j = 1, \ldots, r \}.
$$

Put

$$
\dim \mathcal{L}(D; m_1, \ldots, m_r) = \dim_{\mathbb{K}} \mathcal{L}(D; m_1, \ldots, m_r) - 1,
$$

$$
\text{vdim} \mathcal{L}(D; m_1, \ldots, m_r) = \#D - 1 - \sum_{j=1}^r \binom{m_j + 1}{2},
$$

$$
\text{edim} \mathcal{L}(D; m_1, \ldots, m_r) = \max\{\text{vdim} \mathcal{L}(D; m_1, \ldots, m_r), -1\}.
$$

We say that $\mathcal{L}(D; m_1, \ldots, m_r)$ is special if

$$
\dim \mathcal{L}(D; m_1, \ldots, m_r) > \text{edim} \mathcal{L}(D; m_1, \ldots, m_r).
$$

**Lemma 22.** Let $D \subset \mathbb{Z}^2$ be finite, let $\varphi$ be one of the following maps

$$
\mathbb{Z}^2 \ni (a, b) \mapsto (b, a) \in \mathbb{Z}^2, \quad \mathbb{Z}^2 \ni (a, b) \mapsto (a, -b) \in \mathbb{Z}^2,
$$

$$
\mathbb{Z}^2 \ni (a, b) \mapsto (a, b + a) \in \mathbb{Z}^2, \quad \mathbb{Z}^2 \ni (a, b) \mapsto (a, b + c) \in \mathbb{Z}^2,
$$

where $c \in \mathbb{Z}$. Then

$$
\dim \mathcal{L}(D; m_1, \ldots, m_r) = \dim \mathcal{L}(\varphi(D); m_1, \ldots, m_r)
$$

for any non-negative integers $m_1, \ldots, m_r$. 
Proposition 23. Let \( (p_j)_x \neq 0, (p_j)_y \neq 0 \), where by \((p_j)_x\), \((p_j)_y\) we denote the first and the second coordinate of a point \( p \), respectively. It can be shown that the following linear maps from \( \mathbb{K}[x, x^{-1}, y, y^{-1}] \rightarrow \mathbb{K}[x, x^{-1}, y, y^{-1}] \) given by

\[
\begin{align*}
x^ay^b & \mapsto y^ax^b, \\
x^ay^b & \mapsto x^b y^a
\end{align*}
\]

induce isomorphisms of \( \mathcal{L}(D; m_1, \ldots, m_r) \) with \( \mathcal{L}(\varphi(D); m_1, \ldots, m_r) \), where in the last systems the coordinates of base points \( q_1, \ldots, q_r \) are given by

\[
(q_j)_x = (p_j)_y, (q_j)_y = (p_j)_x, \quad (q_j)_x = (p_j)_y, \quad (q_j)_y = \frac{1}{(p_j)_y},
\]

respectively. To see this, observe that \( \frac{\partial}{\partial y}(f(x, y^{-1})) \) can be written as a linear combination (over \( \mathbb{K}[y] \)) of \( \frac{\partial f}{\partial y}(x, y^{-1}) \) for \( j = 0, \ldots, n \). This suffices to complete the case \((a, b) \mapsto (a, -b)\). The rest of the proof is left to the reader. \( \square \)

**Proposition 23.** Let \( n, b, a, m_1, \ldots, m_r \) be non-negative integers. Let

\[
D = \mathfrak{diag}(1^{\times n}, [2]^{\times n}, \ldots, [b]^{\times n}, [b + 1]^{\times (a + 1)}).
\]

Then

\[
\dim \mathcal{L}_n(a, b; m_1, \ldots, m_r) = \dim \mathcal{L}(D; m_1, \ldots, m_r),
\]

\[
vdim \mathcal{L}_n(a, b; m_1, \ldots, m_r) = vdim \mathcal{L}(D; m_1, \ldots, m_r).
\]

**Proof.** The Hirzebruch surface \( \mathbb{F}_n \) is a toric surface given by the fan generated by \( v_1 = e_1, v_2 = e_2, v_3 = -e_1 + ne_2, v_4 = -e_2 \) (Figure 3; more theory on toric varieties can be found in [Ful 93]). The class \( F \) is given by \( v_3 \) as the class of the curve corresponding to \( v_1 \), similarly \( H \) is given by \( v_4 \). Now, for the line bundle \( aF + bH \) we have

\[
\text{global sections of } aF + bH = \bigoplus_{u \in P_{aF+bH}} \mathbb{K}x^u,
\]

where

\[
P_{aF+bH} = \{ u \in \mathbb{Z}^2 : \langle u, v_i \rangle \geq -a_i \} = \{ (u_x, u_y) \in \mathbb{Z}^2 : -a \leq u_x \leq nu_y, 0 \leq u_y \leq b \}
\]

(see Figure 4), since \( a_1 = a, a_4 = b, a_2 = a_3 = 0 \). The element \( \chi^{(u_x,u_y)} \) is identified
Figure 4. Global sections of $aF + bH$

with the monomial $x^u y^v$ in $K[x, x^{-1}, y, y^{-1}]$. Since there is a Zariski open, non-empty set $U$ on $F_n$ such that $U$ is affine with coordinate ring $K[x, y, x^{-1}, y^{-1}]$, taking $D = P_{aF+bH}$ and points in general position we have

$$\dim L_n(a, b; m_1, \ldots, m_r) = \dim L(D; m_1, \ldots, m_r).$$

By Lemma 22 applying $\varphi : (p, q) \mapsto (p + a + a(b - q), b - q)$ we can transform $P_{aF+bH}$ into the diagram contained in the trapezoid with vertices $(0, 0), (a + nb, 0), (a + nb, b), (nb, b)$ (see Figure 5), which completes the proof. For virtual dimension

Figure 5. The image of $P_{aF+bH}$ by $\varphi$

we use the fact that $\dim L_n(a, b) = \#D - 1$.

Before formulating the next proposition, we need one additional notation. This notation will be used only in the following Proposition 25 and then in Proposition 44.

Definition 24. Let $a_1, \ldots, a_s, u_1, \ldots, u_s$ be non-negative integers. Define

$$\text{diag}(a_1^{u_1}, \ldots, a_s^{u_s}) = \{(x, y) \in \mathbb{N}^2 : u_{x+1} \leq y < a_{x+1} + u_{x+1}\}.$$ 

Proposition 25. Let $b, a, m_1, \ldots, m_r$ be non-negative integers. Let

$$D = \text{diag}(1, \ldots, b, [b+1]^{(a-b+1)}, b^{[1]}, (b-1)^{[2]}, \ldots, 1^{[b]}).$$

Then

$$\dim L_0(a, b; m_1, \ldots, m_r) = \dim L(D; m_1, \ldots, m_r),$$

$$\text{vdim} L_0(a, b; m_1, \ldots, m_r) = \text{vdim} L(D; m_1, \ldots, m_r).$$

Proof. Let $G = \text{diag}([a+1]^{(b+1)})$. From the previous proof and Lemma 22 we have

$$\dim L(G; m_1, \ldots, m_r) = \dim L_0(a, b; m_1, \ldots, m_r).$$

By applying $\varphi : (p, q) \mapsto (p + q, q)$ we obtain $D = \varphi(G)$ (see Figure 6).

Figure 6. Global sections of $aF + bH$ for $F_0$
Theorem 26. Let $D$, $G$ be diagrams, let $m \geq 1$, $p,q \geq 0$. If

- the diagram $G$ can be obtained from $D$ by a sequence of $p$ m-reductions,
- the system $L(G; m^{x_n}, m_1, \ldots, m_r)$ is non-special

then the system $L(D; m^{x(q+p)}, m_1, \ldots, m_r)$ is non-special.

Proof. The proof can be found in [Dum 07b] proof of Theorem 7 and of Proposition 18.

Example 27. We will show that $L_3(2,3;3^4)$ is non-special. By Proposition 23 we have to show that $L_3(D;3^4)$ is empty for $D = \text{diag}(1,1,2,2,3,3,4,4,4)$. By Theorem 26 it is enough to show emptiness of $L(G;3^2)$ for

$$G = \text{red}_3(\text{red}_3(D)) = \text{diag}(1,1,2,2,3,3).$$

The last diagram is 3-reducible, but then the system $L(\text{diag}(1,1,2,2,3,3))$ is non-empty. Instead, using Lemma 22 we can change $\text{diag}(1,1,2,2,3,3)$ into $\text{diag}(2,4,6)$, which can be 3-reduced twice to the empty diagram.

5. Speciality of some homogeneous systems

Proposition 28. The system $L_1(a,b;m^{x_r})$ for $m \leq 10$ is special if and only if it is $-1$-special.

Proof. The surface $F_1$ is the blow-up of $P^2$ in one point, so the proposition follows from [Dum 08] Theorem 3, where it is shown that the SHGH Conjecture holds for quasi-homogeneous systems with homogeneous multiplicity bounded by 10.

Proposition 29. The system $L_n(a,b;m^{x_r})$ for $n \geq 2$ and $b \leq m+1 \leq 11$ is special if and only if it is $-1$-special.

Proof. The proof for the case $r \leq n+1$ and arbitrary $b$ and $m$ can be found in [Laf 02] Proposition 2.7, but there is serious mistake — the line bundle $-K_S$ fails to be nef, where $K_S$ is the canonical bundle on the blow-up of $F_n$ at $r$ points. This is due to the fact that $K_{F_n}^2 = 8$, so $(-K_S)^2 = 8-r$ and this number is negative for $r > 8$ points.

We will give a proof different from that in [Laf 02]. Moreover, we will also consider the case $r \leq n+1$ separately and prove that each system of this type is either non-special or $-1$-special without our additional assumption that $m \leq 10$.

First of all, due to Proposition 14 we will work with the planar system

$$L(a + (n+1)b; a + nb, m^{x_r}, b^{x(n+1)}).$$

During the proof we will write $(k)_{\geq 0}$ for $\max\{k,0\}$.

The first case to consider is $r > n+1$. By Cremona transformations based on the point with the greatest multiplicity, points lying on a line and points with multiplicity $b$ we obtain

$$L(a + (n+1)b - (n+1)m; (a + nb - (n+1)m)_{\geq 0}, m^{x(r-n-1)}, (b - m)^{x(n+1)}).$$

For $b-m \leq 0$ we are done by [Dum 08]. If $b-m = 1$ then either the line $\ell$ supporting $n+1$ points is in the base locus, hence the system is non-special or $-1$-special, or each point lying on this line imposes an independent condition and

$$\dim L(a + (n+1)(b-m); (a + nb - (n+1)m)_{\geq 0}, m^{x(r-n-1)}, 1^{x(n+1)})$$

$$= \dim L(a + (n+1)(b-m); (a + nb - (n+1)m)_{\geq 0}, m^{x(r-n-1)}, 1^{x(n+1)}).$$

If the last system is special then

$$L(a + (n+1)(b-m); (a + nb - (n+1)m)_{\geq 0}, m^{x(r-n-1)})$$

is special and then, by [Dum 08], $-1$-special. This finishes the first case.
The second case is $r \leq n + 1$. As above, by Cremona we can consider 
\[ \mathcal{L}(a + (n + 1)b - rm; (a + nb - rm)_{\geq 0}, (b - m)^{n+1-r}) \].
Now we can remove the fixed part (again consisting of lines) to obtain either the empty system, or the system $L = \mathcal{L}(d; m_0, m_1, \ldots, m_s)$ of the same dimension, where non-negative integers $d, m_0, m_1, \ldots, m_s$ satisfy 
\[ d \geq \sum_{j=1}^{s} m_j \quad \text{and} \quad d \geq m_0 + m_j \quad \text{for} \quad j = 1, \ldots, s. \]
Moreover, we will assume that 
\[ m_1 \geq m_2 \geq \cdots \geq m_s. \]
We will show that the last system is non-special, so by Proposition 11 the system we begin with, is either $-1$-special or non-special.

By a suitable projective change of coordinates we can assume that $p_0 = (0 : 1 : 0)$ and collinear points $q_1, \ldots, q_s$ have coordinates $(w_1 : 0 : 1), \ldots, (w_s : 0 : 1)$. Take $C \in L$ defined by a polynomial $f$. Then $f$ is generated by monomials contained in the set 
\[ D = \{ x^a y^b z^c : a + b + c = d \} = U \cup G \cup (D \setminus (U \cup G)), \]
where 
\[ U = \{ x^a y^b z^c : a + b + c = d, b > d - m \}, \]
\[ G = \{ x^a y^b z^c : a + b + c = d, a < \sum_{j=1}^{s} (m_j - b)_{\geq 0} \} \]
(see Figure 7; the picture is drawn after dehomogenizing with respect to $z$). By our assumption on multiplicities we know that 
\[ \# U = \binom{m_0 + 1}{2}, \quad \# G = \sum_{j=1}^{s} \binom{m_j + 1}{2}, \quad U \cap G = \emptyset. \]
It is enough to show that for fixed coefficients standing by monomials from $D \setminus (U \cup G)$ there exists exactly one $f$, which defines a curve in $L$. Indeed, we can see that $\text{supp}(f) \cap U = \emptyset$. Let $f = f_1 + f_2 + f_3$, where $\text{supp}(f_1) \in G \cap \{ x^a y^b z^c : b = 0 \}$, so $\# \text{supp}(f_1) \leq \sum_{j=1}^{s} m_j$,  
$\text{supp}(f_2) \in (D \setminus G) \cap \{ a^a y^b z^c : b = 0 \}$,  
$\text{supp}(f_3) \in D \cap \{ a^a y^b z^c : b > 0 \}$. We have 
\[ 0 = \frac{\partial^j f}{\partial x^j}(p_k) = \frac{\partial^j f_1}{\partial x^j}(w_k : 0 : 1) + \frac{\partial^j f_2}{\partial x^j}(w_k : 0 : 1) + \frac{\partial^j f_3}{\partial x^j}(w_k : 0 : 1) \]
\[ = \frac{\partial^j (f_1(x : 0 : 1))}{\partial x^j}(w_k) + \frac{\partial^j f_2}{\partial x^j}(w_k : 0 : 1) \]
for \( j = 0, \ldots, m_k - 1, k = 1, \ldots, s \). Since \( \frac{\partial f_k}{\partial x_k}(w_k : 0 : 1) \) is uniquely determined, we use one dimensional interpolation to uniquely determine \( f_1 \). For other monomials in \( G \) we deduce in the analogous way, using induction. Namely, we assume that the coefficients standing by monomials 
\[ \{x^ay^bz^c : x^ay^bz^c \in G, b \leq n - 1\} \]
are uniquely determined, and we will show the same for 
\[ \{x^ay^bz^c : x^ay^bz^c \in G, b = n\} \]
Again, let \( f = f_1 + f_2 + f_3 + f_4 \) for \( \text{supp}(f_1) \in G \cap \{x^ay^bz^c : b = n\} \), \( \text{supp}(f_2) \in (D \setminus G) \cap \{x^ay^bz^c : b = n\} \), \( \text{supp}(f_3) \in \{x^ay^bz^c : b < n\} \), \( \text{supp}(f_4) \in \{x^ay^bz^c : b > n\} \). We have 
\[
0 = \left( \frac{\partial^{i+n}f_1}{\partial x^i \partial y^n} + \frac{\partial^{i+n}f_2}{\partial x^i \partial y^n} + \frac{\partial^{i+n}f_3}{\partial x^i \partial y^n} + \frac{\partial^{i+n}f_4}{\partial x^i \partial y^n} \right) (w_k : 0 : 1)
\]
\[
= n! \frac{\partial f_1(x : 0 : 1)}{\partial x^i}(w_k) + \frac{\partial^{i+n}f_2}{\partial x^i \partial y^n}(w_k : 0 : 1) + \frac{\partial^{i+n}f_3}{\partial x^i \partial y^n}(w_k : 0 : 1)
\]
for \( k = 1, \ldots, s \) such that \( m_k > n \) and \( j = 0, \ldots, m_k - n - 1 \). By assumptions, the contribution from \( f_2 \) and \( f_4 \) is fixed and we use interpolation.

**Proposition 30.** The system \( \mathcal{L}_0(a, b; m^{x_B}) \) for \( \min\{a, b\} \leq m \leq 10 \) is special if and only if it is \(-1\)-special.

**Proof.** The above system is equivalent to \( \mathcal{L}(a + b; a, b, m^{x_B}) \), so, by Cremona, we get 
\[
\mathcal{L}(a + b - m; (a - m)_{\geq 0}, (b - m)_{\geq 0}, m^{x_B - 1})
\]
and we use [Dum 08] (for quasihomogeneous) or [Dum 07a, Theorem 32] (for homogeneous system).

6. SEQUENCES OF REDUCTIONS

**Definition 31.** Let \( m \geq 2 \), let \( h > m \) be integers. We say that \((a_1, \ldots, a_{m-1})\) is an admissible \( h\)-(1,...,1)-tail for multiplicity \( m \) if there exists \( k \geq 0 \) such that the diagram \( D_1 = \text{diag}(a_1, \ldots, a_{m-1}) \) can be obtained from \( D_2 = \text{diag}(h)^{x_B}, b_1, \ldots, b_m \) by a sequence of \( m \)-reductions.

**Example 32.** Let us see how one can enumerate all admissible 8-([0]3)-tails for multiplicity 4. We begin with \((a_1, a_2, a_3)\) equal to \((0, 0, 0)\), \((8, 0, 0)\), \((8, 8, 0)\) and \((8, 8, 8)\), which can be obtained without performing any reduction. Now observe that \( \text{diag}(8, 8, 8) \) can be 4-reduced to \( \text{diag}(6, 4, 2) \), so \((6, 4, 2)\) is also an admissible tail. Now, each time we have an admissible tail, we can add \( 8 \) at the beginning and reduce until the fourth number disappears. This gives the sequence
\[
\text{diag}(6, 4) \xrightarrow{\text{add}} \text{diag}(8, 6, 4, 2) \xrightarrow{\text{red}} \text{diag}(7, 3) \xrightarrow{\text{add}} \text{diag}(8, 7, 3) \xrightarrow{\text{add}} \text{diag}(8, 8, 7, 3) \xrightarrow{\text{add}} \text{diag}(8, 8, 8, 3) \xrightarrow{\text{add}} \text{diag}(8, 8, 8, 7, 3) \xrightarrow{\text{add}} \text{diag}(8, 8, 8, 8, 3) \xrightarrow{\text{add}} \ldots
\]
Observe that now our procedure will follow the loop, so nothing more will appear. Each diagram standing before one of the \( \xrightarrow{\text{add}} \) arrows gives an admissible tail.

**Definition 33.** Let \( m \geq 2 \), let \( a_1, \ldots, a_m \) be such that \( \text{diag}(a_1, \ldots, a_m) \) is \( m \)-reducible. Let \( \ell, k \) be nonnegative integers. We say that \( \text{diag}(b_1, \ldots, b_m, x^{[\ell]}x^k) \) is a symbolic \( m \)-reduction of \( \text{diag}(a_1, \ldots, a_m, x^k) \) (\( x \) is just the symbol without
value) if and only if there exists \(c_1, \ldots, c_\ell\) such that \(m + 1 \geq c_1 \geq \cdots \geq c_\ell\) and 
\[ \text{diag}(a_1, \ldots, a_m, c_1, \ldots, c_\ell) \ \text{is} \ m\text{-reducible}, \]
\[ \text{red}_m(\text{diag}(a_1, \ldots, a_m, c_1, \ldots, c_\ell)) = \text{diag}(b_1, \ldots, b_m, d_1, \ldots, d_\ell) \]
(with, possibly, some of \(b_j\)'s and \(d_j\)'s equal 0) satisfying 
\[ k = \begin{cases} 0, & d_1 = 0, \\ \max\{j : d_j > 0\}, & d_1 > 0. \end{cases} \]

Example 34. Let us enumerate all symbolic 3-reductions for \(D = \text{diag}(6, 6, 7, x, x)\) (i.e. \(\ell = 2\)). This is just a straightforward calculation:
\[
\begin{align*}
\text{diag}(6, 6, 7, 4, 4) & \rightarrow \text{diag}(6, 6, 6, 2, 1) \rightarrow \text{diag}(6, 6, 6, x, x), \\
\text{diag}(6, 6, 7, 4, 3) & \rightarrow \text{diag}(6, 6, 6, 2) \rightarrow \text{diag}(6, 6, 6, x), \\
\text{diag}(6, 6, 7, 4, 2) & \rightarrow \text{diag}(6, 6, 6, 1) \rightarrow \text{diag}(6, 6, 6, x), \\
\text{diag}(6, 6, 7, 4, 1) & \rightarrow \text{diag}(6, 6, 5, 1) \rightarrow \text{diag}(6, 6, 5, x), \\
\text{diag}(6, 6, 7, 4) & \rightarrow \text{diag}(6, 5, 5, 1) \rightarrow \text{diag}(6, 5, 5, x), \\
\text{diag}(6, 6, 7, 3, 3) & \rightarrow \text{diag}(6, 6, 6, 1) \rightarrow \text{diag}(6, 6, 6, x), \\
\text{diag}(6, 6, 7, 3, 2) & \rightarrow \text{diag}(6, 6, 6), \\
\text{diag}(6, 6, 7, 3) & \rightarrow \text{diag}(6, 5, 5), \\
\text{diag}(6, 6, 7, 2) & \rightarrow \text{diag}(6, 5, 4), \\
\text{diag}(6, 6, 7) & \rightarrow \text{diag}(5, 4, 4).
\end{align*}
\]

Definition 35. Let \(m \geq 2\), let \(a_1, \ldots, a_m\) be such that \(\text{diag}(a_1, \ldots, a_m)\) is \(m\)-reducible. We say that \(D = \text{diag}(b_1, \ldots, b_{m-1})\) is an admissible \((a_1, \ldots, a_m)\)-tail for multiplicity \(m\) if \(D\) can be obtained from \(\text{diag}(a_1, \ldots, a_m, [x]^{(m-1)})\) by a sequence of symbolic \(m\)-reductions.

Example 36. Let us show that \(\text{diag}(6, 4)\) is an admissible \((6, 6, 7)\)-tail for multiplicity 3. Indeed,
\[
\begin{align*}
\text{diag}(6, 6, 7, x, x) & \xrightarrow{\text{symred}} \text{diag}(6, 6, 6, x, x) \xrightarrow{\text{symred}} \text{diag}(6, 6, 5, x, x) \\
& \xrightarrow{\text{symred}} \text{diag}(6, 6, 4, x, x) \xrightarrow{\text{symred}} \text{diag}(6, 6, 3, x) \xrightarrow{\text{symred}} \text{diag}(6, 4).
\end{align*}
\]

Observe that \(\xrightarrow{\text{red}}\) acts as a function, while \(\xrightarrow{\text{symred}}\) is only a relation — there are, usually, several possible symbolic reductions. We will use \(\text{symred}(D)\) to denote the set of all symbolic reductions of \(D\). Given \(D\), we can find all elements in \(\text{symred}(D)\) in an algorithmic way, and since every admissible \((a_1, \ldots, a_m)\)-tail belongs to
\[ \text{symred}(\ldots \text{symred}(\text{diag}(a_1, \ldots, a_m, [x]^{(m-1)})) \ldots), \]
where the number of symbolic reductions is bounded from above (the bound depends on \(m\) and \((a_1, \ldots, a_m)\)), we can enumerate all admissible \((a_1, \ldots, a_m)\)-tails.

Proposition 37. Let \(m \geq 2\), let \(D = \text{diag}(a_1, \ldots, a_k)\) for \(k \geq m\) and 

- \(a_1 \geq m + 1\),
- \(a_{j+1} \in \{a_j - 1, a_j, a_j + 1\}\) for \(j = 1, \ldots, k - 1\),
- if \(a_{j+1} = a_j + 1\) then \(a_j \geq 2m - 1\) for \(j = 1, \ldots, k - 1\),
- if \(a_{j+1} = a_j\) then \(a_j \geq m\) for \(j = 1, \ldots, k - 1\).
Then $D$ can be reduced by a sequence of $m$-reductions to a diagram $G$, which is an admissible $(a_1, \ldots, a_m)$-tail for multiplicity $m$.

Proof. We will reduce successively, beginning with $D$. Let us assume that we have obtained $\text{diag}(b_1, \ldots, b_k)$, which cannot be $m$-reduced. Hence

$$0 < b_j \leq b_{j+1} \leq m - 1$$

for some $j$. We have three possibilities:

- $a_{j+1} = a_j - 1$. Since the $(j + 1)$th layer would be reduced stronger than $j$th, we would have $b_{j+1} < b_j$;
- $a_{j+1} = a_j$. Now $b_j < a_j$ since $a_j \geq m$, so the $j$th layer must be reduced at least once and again $b_{j+1} < b_j$;
- $a_{j+1} = a_j + 1$. Now the difference between $a_j$ and $b_j$ is at least $m$, so the $j$th layer must be reduced at least twice and again $b_{j+1} < b_j$.

So we can reduce $D$ to some $G = (e_1, \ldots, e_{m-1})$. We have to show that $G$ is an admissible $(a_1, \ldots, a_m)$-tail for multiplicity $m$.

Define

$$\text{symb}(\text{diag}(d_1, \ldots, d_m, d_{m+1}, \ldots, d_k)) = \text{diag}(d_1, \ldots, d_m, [x]^{k-m})].$$

Observe that if $E = \text{diag}(d_1, \ldots, d_m, e_1, \ldots, e_k)$ is a diagram which can be $m$-reduced then

$$\text{symb}(\text{red}_m(E)) = \text{symb}(\text{red}_m(\text{diag}(d_1, \ldots, d_m, \min\{e_1, m+1\}, \ldots, \min\{e_k, m+1\}))).$$

The last diagram belongs to $\text{symbred}_m(\text{symb}(E))$. Let $G = \text{red}^{(p)}_m(D)$, where $\text{red}^{(p)}_m$ denotes the $m$-reduction performed $p$ times. From (1) we have

$$G = \text{symb}(G) = \text{symb}(\text{red}^{(p)}_m(D)) \in \text{symbred}^{(p)}(\text{symb}(D)).$$

Since symbolic reductions performed on $\text{diag}(a_1, \ldots, a_m, [x]^{s})$ for $s \geq m$ does not change $(a_1, \ldots, a_m)$, we have

$$\text{symbred}^{(p)}(\text{symb}(D)) \subset \bigcup_{q=0}^{\infty} \text{symbred}^{(q)}(\text{diag}(a_1, \ldots, a_m, [x]^{s-m-1})))$$

which completes the proof. □

7. Non-speciality by reductions

We are going to show the non-speciality of a large class of systems not covered by Propositions 28, 29 and 30. In fact we want to construct a finite set $E$ of systems and prove that for $L \notin E$ the Conjecture holds. We will provide conditions on $m$, $n$, $b$ and $a$ such that, under these conditions, the diagram for $L(a, b)$, i.e $\text{diag}([0]^n, \ldots, [b]^n, [b+1]^{(n+1)})$ can be divided into three parts (see Figure 8) $D_1 + D_2 + D_3$ such that $D_2$ is fixed, while $D_1$ and $D_3$ can be reduced ($D_1$ from the left, $D_3$ from the right) to much smaller diagrams $D'_1$ and $D'_3$. We will show that

![Division of a diagram](image-url)
it is possible to enumerate all reductions of $D_1$ and $D_3$ and show that in each case the system $\mathcal{L}(D'_1 + D_2 + D'_3; m \times r)$ is non-special. Then we will apply Theorem 26.

For example, for $n \geq 4$ and $b \geq 8$ the diagram can be always written as follows:

$$D_1 + \text{diag}(8 \times 4) + D_3.$$ 

It is rather clear that we can 3-reduce the above to

$$\text{diag}(a_1, a_2) + \text{diag}(8 \times 4) + \text{diag}(b_1, b_2),$$

where the set of possible $a_1, a_2, b_1, b_2$ is finite.

To make the understanding of our proof easier, we present the outline on Figure 9.

**Figure 9. The way of proving the main conjecture**
Define (for a diagram $D$ and $m \geq 2$) the following number:

$$p(D) = \left\lceil \frac{\#D}{m+1} \right\rceil.$$

Observe that if $\mathcal{L}(D; m \times p(D))$ and $\mathcal{L}(D; m \times (p(D)+1))$ are non-special then $\mathcal{L}(D; m \times r)$ is non-special for $r \geq 0$.

For $D = \text{diag}(a_1, \ldots, a_n)$ let $\text{rev}(D) = \text{diag}(a_n, \ldots, a_1)$.

**Proposition 38.** Let $m$, $N$, $B$ be integers, $m \geq 2$, $N \geq m$, $B \geq m+2$. There exists the finite set $\mathcal{D}$ of diagrams, such that if for all $D \in \mathcal{D}$ both systems $\mathcal{L}(D; m \times p(D))$ and $\mathcal{L}(D; m \times (p(D)+1))$ are non-special then for any $n \geq N$, $b \geq B$, $a \geq 0$, $r \geq 0$ the system $\mathcal{L}_n(a, b; m \times r)$ is non-special. Moreover, the set $\mathcal{D}$ can be found algorithmically.

**Proof.** The idea is to choose $\mathcal{D}$ to be the set of diagrams with the following property: any diagram for $\mathcal{L}_n(a, b; m \times r)$, i.e. diagram

$$D = \text{diag}([1]^{\times n}, [2]^{\times n}, \ldots, [b]^{\times n}, b+1, [b+1]^{\times n})$$

can be reduced $r$ times, or can be reduced to a diagram from $\mathcal{D}$. If this is the case then we conclude by Theorem 28. Of course, we use $m$-reductions. We will show how $D$ can be reduced, and simultaneously we will construct $\mathcal{D}$.

We begin with $m$-reducing from the left, the first layer being the lowest one (see Figure 10). After performing $n$ such reductions, we obtain

![Figure 10. Reduction from the left](image-url)

$$D_6 = \text{diag}([m+1]^{\times n}, [m+2]^{\times n}, \ldots, [b]^{\times n}, [b+1]^{(a+1)})].$$

We must deal with two cases, $B \geq 2m-1$ and $B < 2m-1$, separately.

**Case** $B \geq 2m-1$. For $b \geq B \geq 2m-1$ we can write

$$D_6 = \text{diag}([m+1]^{\times n}, \ldots, [2m-2]^{\times n}, [2m-1]^{\times n}, \ldots, [b+1]^{(a+1)}].$$

We will show that this diagram can be reduced to

$$D_5 = \text{diag}([m+1]^{\times n}, \ldots, [2m-2]^{\times n}, a_1, \ldots, a_{m-1}),$$

where $(a_1, \ldots, a_{m-1})$ is an admissible $(2m-1)^{\times m}$-tail. To see the above, take

$$G = \text{diag}([2m-1]^{\times n}, \ldots, [b+1]^{(a+1)}])$$

and use Proposition 37. It means, in particular, that $\text{diag}(a_1, \ldots, a_{m-1})$ can be obtained from $\text{diag}([2m-1]^{\times m}, [x]^{(m-1)})$ by a sequence of symbolic reductions. Put

$$D_5 = \{G : G \text{ is an admissible } (2m-1)^{\times m}\}.$$

Now take

$$D_4 = \text{rev}(D_5) = \text{diag}(a_{m-1}, \ldots, a_1, [2m-2]^{\times n}, \ldots, [m+1]^{\times n}).$$
As in the previous case, we repeat reducing together with generating all admissible $D$

For an admissible $(m + 1)$-$(\{0\} \times (m - 1))$-tail $(b_1, \ldots, b_{m - 1})$. Taking

$$D_3 = \{ \text{all admissible } (m + 1)\text{-}(\{0\} \times (m - 1))\text{-tails} \}$$

we will have

$$D_3 \in \{ \text{rev}(G) + \text{diag}([2m - 2]^{x_n}, \ldots, [m + 2]^{x_n}) + H : G \in D_5, H \in D_3 \}.$$ 

Again, $D_3$ can be reduced to

$$D_2 = \text{diag}(a_{m-1}, \ldots, a_1, [2m - 2]^{x_n}, \ldots, [m + 3]^{x_n}, c_1, \ldots, c_{m-1}),$$

for an admissible $(m + 2)$-$(b_1, \ldots, b_{m - 1})$-tail $(c_1, \ldots, c_{m - 1})$. Taking

$$D_2 = \{ \text{all admissible } (m + 2)\text{-G-tails } : G \in D_3 \}$$

we will have

$$D_2 \in \{ \text{rev}(G) + \text{diag}([2m - 2]^{x_n}, \ldots, [m + 3]^{x_n}) + H : G \in D_5, H \in D_2 \}.$$ 

This can be repeated for each $j = m + 3, \ldots, 2m - 3$ until the following is obtained:

$$D_1 = \text{diag}(a_{m-1}, \ldots, a_1, [2m - 2]^{x_n}, d_1, \ldots, d_{m-1}),$$

$$D_1 = \{ \text{all admissible } (2m - 3)\text{-G-tails } : G \text{ in the previous set } D \},$$

$$D_1 \in \{ \text{rev}(G) + \text{diag}([2m - 2]^{x_n}) + H : G \in D_5, H \in D_1 \}.$$ 

Now, we do the above once more for $2m - 2$, but leaving the part $\text{diag}([2m - 2]^{x_n})$ untouched, in order to finish with a diagram big enough to obtain non-speciality.

So we obtain

$$D_0 = \text{diag}(a_{m-1}, \ldots, a_1, [2m - 2]^{x_n}, e_1, \ldots, e_{m-1}),$$

$$D_0 = \{ \text{all admissible } (2m - 2)\text{-G-tails } : G \in D_1 \},$$

$$D_0 \in \{ \text{rev}(G) + \text{diag}([2m - 2]^{x_n}) + H : G \in D_5, H \in D_0 \}.$$ 

Since $D_0$ has been obtained from $D$ by a sequence of $m$-reductions, putting

$$D = \{ \text{rev}(G) + \text{diag}([2m - 2]^{x_n}) + H : G \in D_5, H \in D_0 \};$$

we are done.

Case $B < 2m - 1$. For each $b \in \{ B, \ldots, 2m - 2 \}$ we do the following. Put

$$D_6 = \text{diag}([m + 1]^{x_n}, \ldots, [b + 1]^{x_{(a+1)}}).$$

By Proposition 33, this diagram can be reduced to

$$D_5 = \text{diag}([m + 1]^{x_n}, \ldots, [b]^{x_n}, a_1, \ldots, a_{m-1}),$$

where $(a_1, \ldots, a_{m-1})$ is an admissible $(b + 1)$-$(\{0\} \times (m - 1))$-tail. Put

$$D_5 = \{ G : G \text{ is an admissible } (b + 1)\text{-}(\{0\} \times (m - 1))\text{-tail} \}.$$ 

Now take

$$D_4 = \text{rev}(D_5) = \text{diag}(a_{m-1}, \ldots, a_1, [b]^{x_n}, \ldots, [m + 1]^{x_n}).$$

As in the previous case, we repeat reducing together with generating all admissible $j$-G-tails, until the following is obtained:

$$D_1 = \text{diag}(a_{m-1}, \ldots, a_1, [b]^{x_n}, d_1, \ldots, d_{m-1}),$$

$$D_1 = \{ \text{all admissible } (b - 1)\text{-G-tails } : G \text{ in the previous set } D \},$$

$$D_1 \in \{ \text{rev}(G) + \text{diag}([b]^{x_n}) + H : G \in D_5, H \in D_1 \}.$$ 

Now, as before, we do the above once more for $b$, but leaving the part $\text{diag}([b]^{x_n})$ untouched. □
Example 39. Let us show how we reduce for \((m, N, B) = (4, 10, 7)\) and \((m, N, B) = (4, 12, 6)\). In the first case we consider \(m = 4, n \geq 10, b \geq 7, a \geq 0\) and take
\[
D = \text{diag}([1]^{\times n}, \ldots, [6]^{\times n}, [b + 1]^{\times (a+1)}).
\]
In order to make reductions, we consider
\[
D = \text{diag}([1]^{\times n}, \ldots, [4]^{\times n}) + \text{diag}([5]^{\times n}) + \text{diag}([6]^{\times (n-10)}) + \text{diag}([6]^{\times 10}) + \text{diag}([7, 7, 7, x, x, x]).
\]
The diagram will be reduced from left and right, without touching \(\text{diag}([6]^{\times 10})\).

In the second case we take \(m = 4, n \geq 12, b = 6, a \geq 0\),
\[
D = \text{diag}([1]^{\times n}, \ldots, [6]^{\times n}, [7]^{\times (a+1)}).
\]
In order to make reductions, we consider
\[
D = \text{diag}([1]^{\times n}, \ldots, [4]^{\times n}) + \text{diag}([5]^{\times n}) + \text{diag}([6]^{\times (n-12)}) + \text{diag}([6]^{\times 12}) + \text{diag}([7]^{\times (a+1)}).
\]
Again, \(\text{diag}([6]^{\times 12})\) remains untouched during reductions.

Proposition 40. Let \(m, n, B\) be integers, \(m \geq 2, n \geq 2, B \geq 2m - 1\). There exists the finite set \(\mathcal{D}\) of diagrams, such that if for all \(D \in \mathcal{D}\) both systems \(L(D; m^{\times p(D)})\) and \(L(D; m^{\times (p(D)+1)})\) are non-special then for any \(b \geq B, a \geq 0, r \geq 0\) the system \(L_n(a; b; m^{\times r})\) is non-special. Moreover, the set \(\mathcal{D}\) can be found algorithmically.

Proof. Take \(G = \text{diag}([1]^{\times n}, \ldots, [B]^{\times n}, B + 1)\), let \(k = nB + 1 - m\). Write
\[
G = \text{diag}(e_1, \ldots, e_k) + \text{diag}(d_1, \ldots, d_m).
\]
Let
\[
\mathcal{D} = \{\text{diag}(e_1, \ldots, e_k) + E : E \text{ is an admissible (}d_1, \ldots, d_m\)^{-}\text{tail}\}.
\]
Now take \(b, a\) and \(r\) as above, let
\[
D = \text{diag}([1]^{\times n}, \ldots, [b]^{\times n}, [b + 1]^{\times (a+1)}) = G + \text{diag}(\ldots).
\]
Since \(b \geq 2m - 1\) we can use Proposition \ref{prop:admissible} to show that \(D\) can be reduced to the diagram
\[
D_1 = \text{diag}(e_1, \ldots, e_k) + \text{diag}(a_1, \ldots, a_{m-1}),
\]
where \((a_1, \ldots, a_{m-1})\) is an admissible \((d_1, \ldots, d_m)^{-}\text{tail}\). Observe that \(D_1 \in \mathcal{D}\) and conclude with Theorem \ref{thm:finite}.

Example 41. Let \(m = 4, n = 4, B = 7\). Take \(b \geq 7, a \geq 0\) and consider
\[
D = \text{diag}([1]^{\times 4}, \ldots, [b]^{\times 4}, [b + 1]^{\times (a+1)}).
\]
which can be written as
\[
\text{diag}([1]^{\times 4}, \ldots, [6]^{\times 4}, 7) + \text{diag}(7, 7, 7, 8, x, x, x) + \text{diag}(\ldots).
\]
Now the left hand side remains untouched, while the right hand side will be reduced.

Proposition 42. Let \(m, n, b, A\) be integers, \(m \geq 2, n \geq 2, b \geq m, A \geq 0\). There exists the finite set \(\mathcal{D}\) of diagrams, such that if for all \(D \in \mathcal{D}\) both systems \(L(D; m^{\times p(D)})\) and \(L(D; m^{\times (p(D)+1)})\) are non-special then for any \(a \geq A, r \geq 0\) the system \(L_n(a; b; m^{\times r})\) is non-special. Moreover, the set \(\mathcal{D}\) can be found algorithmically.
Proof. Let
\[ \mathcal{D} = \{ \text{diag}([1]^{\times n}, \ldots, [b]^{\times n}, [b+1]^{\times (A+1)}) + G : G \text{ is an admissible } (b+1)-(][0]^{\times (m-1)}) \text{-tail}\}. \]

Now take \(a\) and \(r\) as above, let
\[ D = \text{diag}([1]^{\times n}, \ldots, [b]^{\times n}, [b+1]^{\times (a+1)}). \]
Since \(b \geq m\) we can use Proposition \(37\) to show that \(D\) can be reduced to the diagram
\[ D_1 = \text{diag}([1]^{\times n}, \ldots, [b]^{\times n}, [b+1]^{\times (A+1)}, d_1, \ldots, d_{m-1}), \]
where \((d_1, \ldots, d_{m-1})\) is an admissible \((b+1)-(][0]^{\times (m-1)})\)-tail. Observe that \(D_1 \in \mathcal{D}\) and conclude using Theorem \(26\). \(\square\)

Example 43. Let \(m = 4\), \(n = 3\), \(b = 6\), \(A = 1\). Take \(a \geq 1\) and consider
\[ D = \text{diag}([1]^{\times 3}, \ldots, [6]^{\times 3}, [7]^{\times (a+1)}), \]
which can be written as
\[ \text{diag}([1]^{\times 3}, \ldots, [6]^{\times 3}, 7, 7) + \text{diag}([7]^{\times (a-1)}). \]

Now the left hand side remains untouched, while the right hand side will be reduced.

**Proposition 44.** Let \(m, B\) be integers, \(m \geq 2\), \(B \geq 3(m-1)\). There exists the finite set \(\mathcal{D}\) of diagrams, such that if for all \(D \in \mathcal{D}\) both systems \(L(D; m^{\times (D)})\) and \(L(D; m^{\times (p(D)+1)})\) are non-special then for any \(a \geq b \geq B\), \(r \geq 0\) the system \(L_0(a, b; m^{\times r})\) is non-special. Moreover, the set \(\mathcal{D}\) can be found algorithmically.

**Proof.** It is enough to take
\[ \mathcal{D} = \{ \text{diag}(1, \ldots, B - m + 1) + G : G \text{ is an admissible } (B - m + 2, \ldots, B + 1)\text{-tail}\}. \]
Indeed, taking \(b\), \(a\) and \(r\) as above, let
\[ D = \text{diag}(1, \ldots, b, [b+1]^{\times (a-b+1)}, b^{11}, \ldots, 1^{1b}) = \text{diag}(1, \ldots, B - m + 1) + \text{diag}(B - m + 2, \ldots, B + 1, \ldots) \]
be the diagram for \(L_0(a, b)\) (see Proposition \(23\)). Observe that reducing \((b^{11}, \ldots, 1^{1b})\) is equivalent to reducing \((b, \ldots, 1)\), and this part of the diagram will surely be reduced. Again, by Proposition \(37\) \(D\) can be reduced to a diagram belonging to \(\mathcal{D}\), since, by assumption, \(B - m + 2 \geq 2m - 1\). \(\square\)

**Proposition 45.** Let \(m, b, A\) be integers, \(A \geq b \geq m \geq 2\). There exists the finite set \(\mathcal{D}\) of diagrams, such that if for all \(D \in \mathcal{D}\) both systems \(L(D; m^{\times (D)})\) and \(L(D; m^{\times (p(D)+1)})\) are non-special then for any \(a \geq A\), \(r \geq 0\) the system \(L_0(a, b; m^{\times r})\) is non-special. Moreover, the set \(\mathcal{D}\) can be found algorithmically.

**Proof.** It is enough to take
\[ \mathcal{D} = \{ \text{diag}([b+1]^{\times (A+1)}) + G : G \text{ is an admissible } (b+1)-(][0]^{\times (m-1)})\text{-tail}\}. \]
Indeed, take \(a\) and \(r\) as above and let
\[ D = \text{diag}([b+1]^{\times (a+1)}) = \text{diag}([b+1]^{\times (A+1)}) + \text{diag}(b + 1, b + 1, \ldots) \]
Again, by Proposition \(37\) \(D\) can be reduced to a diagram belonging to \(\mathcal{D}\). \(\square\)
Proposition 46. For the following values of \( m, N, \) and \( B \) the set \( D \) from Proposition 38 contains only non-special diagrams:

\[
\begin{array}{|c|c|c|c|c|c|c|}
\hline
m & 2 & 3 & 4 & 5 & 6 & 7 & 8 \\
\hline
N \text{ for } B > m + 2 & 2 & 5 & 11 & 11 & 22 & 25 & 41 \\
N \text{ for } B = m + 2 & 2 & 5 & 16 & 30 & 51 & 85 & 127 \\
\hline
\end{array}
\]

Proof. The proof was completed using suitable computer programs. First, one has to create the set \( D \). Next, for each diagram \( D \in D \) a computation of the rank of two interpolation matrices (for \( p(D) \) and \( p(D) + 1 \) points of multiplicity \( m \)) shows that \( D \) is non-special. All programs can be downloaded from [Dum 09], together with files containing the results of running them by the author. \( \square \)

Proposition 47. For the following values of \( m, n, \) and \( B \) the set \( D \) from Proposition 40 contains only non-special diagrams:

\[
\begin{array}{|c|c|c|c|c|c|c|c|c|}
\hline
m & 3 & 4 & 4 & 4 & 5 & 5 & 5 \\
n & 2, 3, 4 & 2, 3, 4, \ldots, 10 & 2, 3, 4, \ldots, 10 \\
B & 6 & 6 & 9 & 9 & 11 & 10 & 9 \\
\hline
m & 6 & 6 & 7 & 7 & 8 & 8 \\
n & 2, 3, 4, \ldots, 21 & 2, 3, \ldots, 24 & 2, 3, \ldots, 40 \\
B & 13 & 12 & 11 & 15 & 13 & 17 & 15 \\
\hline
\end{array}
\]

Proof. Again we use suitable computer programs. \( \square \)

Observe that only finite number of triples \((m, n, b)\) satisfying

\[2 \leq m \leq 8, \quad n \geq 2, \quad b \geq m + 2\]

are not covered by the two previous Propositions. We will not list all of them, but only present the number of them:

\[
\begin{array}{|c|c|c|c|c|c|}
\hline
m & 2 & 3 & 4 & 5 & 6 & 7 & 8 \\
\hline
\# \text{ of triples} & 0 & 3 & 17 & 40 & 92 & 154 & 321 \\
\hline
\end{array}
\]

Again using suitable computer programs we proved the following:

Proposition 48. For every triple \((m, n, b)\) not covered by Proposition 46 or Proposition 47 there exists \( A \) such that the set \( D \) from Proposition 42 contains only non-special diagrams. The greatest value of \( A \) is shown in the table below:

\[
\begin{array}{|c|c|c|c|c|c|}
\hline
m & 2 & 3 & 4 & 5 & 6 & 7 & 8 \\
\hline
\max A & 0 & 0 & 1 & 3 & 13 & 22 & 33 \\
\hline
\end{array}
\]

Proposition 49. For the following values of \( m \) and \( B \) the set \( D \) from Proposition 44 contains only non-special diagrams:

\[
\begin{array}{|c|c|c|c|c|c|}
\hline
m & 2 & 3 & 4 & 5 & 6 & 7 & 8 \\
\hline
B & 6 & 9 & 12 & 15 & 19 & 21 & 24 \\
\hline
\end{array}
\]

Proof. Again we use suitable computer programs. Observe that \( B = 3m \) is sufficient for all checked cases except for \( m = 6 \). There are no geometrical explanation to this fact (all systems \( L_0(a, b; 6 \times r) \) with \( a, b \geq 18 \) are non-special), but the system \( L(D; 6 \times 6^x) \) for

\[D = \text{diag}(1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 12, 11, 10, 2)\]

is special. \( \square \)
Proposition 50. For the following values of $m$, $b$, and $A$ the set $D$ from Proposition 45 contains only non-special diagrams:

Proof. Again we use suitable computer programs. □

8. Final cases

There are some quadruples $(m, n, a, b)$ not covered by previous Propositions. For each of these we must find $r_1$ and $r_2$ such that for all $r \leq r_1$ and all $r \geq r_2$ the system $L_n(a,b;m \times r)$ is non-special. This can be done by direct computations. If $r_1 + 1 < r_2$ then we must check if all systems for $r_1 < r < r_2$ are $-1$-special. This was done by a computer program. Here we present the number of final $(m, n, a, b)$'s together with the number of special systems found, depending on $m$:

<table>
<thead>
<tr>
<th>$m$</th>
<th>2 3 4 5 6 7 8</th>
</tr>
</thead>
<tbody>
<tr>
<td>number of cases</td>
<td>0 2 11 30 90 187 353</td>
</tr>
<tr>
<td>number of special systems</td>
<td>0 1 5 12 37 70 134</td>
</tr>
</tbody>
</table>

While checking $-1$-speciality we considered only $-1$-systems with imposed base points in general position, i.e. $L(d;m_1,\ldots,m_r,k_1,\ldots,k_s)$ satisfying

$$\dim L(d;m_1,\ldots,m_r,k_1,\ldots,k_s) = \dim L(d;m_1,\ldots,m_r,k_1,\ldots,k_s).$$

Also in Propositions 28, 29 and 30 we used $-1$-systems with imposed base points in general position.
