Abstract

In this article, we introduce the class of semimonotone star ($E_0^s$) matrices. We establish the importance of $E_0^s$-matrix in the context of complementarity theory. We illustrate that the principal pivot transform of $E_0^s$-matrix is not necessarily $E_0^s$. However, $\tilde{E}_0^s$-matrix, a subclass of $E_0^s$-matrices with some additional conditions is in $E_0^f$ by showing this class in $P_0$. If $A \in \tilde{E}_0^s \cap P_0$, then LCP($q, A$) can be processable by Lemke’s algorithm. We show the condition for which the solution set of LCP($q, A$) is bounded and stable under $\tilde{E}_0^s$-property. We propose an algorithm based on interior point method to solve LCP($q, A$) given $A \in \tilde{E}_0^s$.

Keywords: Linear complementarity problem, principal pivot transform, Lemke’s algorithm, interior point method, semimonotone star matrix, $\tilde{E}_0^s$-matrix.

AMS subject classifications: 90C33, 90C90.

1 Introduction

The concept of pseudomonotone or copositive star matrices on a closed convex cone with respect to complementarity condition was studied by Gowda [4]. Copositive star matrices are of crucial importance in deriving criterion for $P_0 \cap Q_0$. The properties of copositive star matrices are well studied in the literature of linear complementarity problem. A star matrix [10] is defined as any point $x$ from solution set of LCP($q, A$) satisfies $A^T x \leq 0$. Bazan and Lopez [10] studied $F_1$-matrix in the context of star matrix and proved the necessary and sufficient conditions of $F_1$-properties. In linear complementarity theory, much of the research is devoted to find out constructive
characterization of $Q_0$ and $Q$-matrices. The set $K(A)$ denotes as a closed cone containing the nonnegative orthant $R^n_+$. Eaves [9] showed that $A \in Q_0$ if and only if $K(A)$ is convex. A subclass $Q$ of $Q_0$ is defined by the property that $A \in Q$ if and only if $K(A) = R^n$. Aganagic and Cottle [1] showed that Lemke’s algorithm processes $LCP(q, A)$ if $A \in P_0 \cap Q_0$.

Many of the concepts and algorithms in optimization theory are developed based on principal pivot transform (PPT). The notion of PPT is originally motivated by the well-known linear complementarity problem. The class of semimonotone matrices ($E_0$) introduced by Eaves [9] (denoted by $L_1$ also) consists of all real square matrices $A$ such that $LCP(q, A)$ has a unique solution for every $q > 0$. Cottle, Pang and Stone [6] introduced the notion of a fully semimonotone matrix ($E_f$) by requiring that every PPT of such a matrix is a semimonotone matrix. For the class $E_f$ with some additional conditions, $LCP(q, A)$ has a unique solution. Stone studied various properties of $E_f$ and conjectured that $E_f$ with $Q_0$-property are contained in $P_0$. The linear complementarity problem is a combination of linear and nonlinear system of inequalities and equations. The problem may be stated as follows: Given $A \in R^{n \times n}$ and a vector $q \in R^n$, the linear complementarity problem $LCP(q, A)$ is the problem of finding a solution $w \in R^n$ and $z \in R^n$ to the following system:

\begin{align}
    w - Az &= q, \quad w \geq 0, \quad z \geq 0 \\
    w^T z &= 0
\end{align}

Suppose $FEA(q, A) = \{z : q + Az \geq 0\}$ and $SOL(q, A) = \{z \in FEA(q, A) : z^T(q + Az) = 0\}$ denote feasible and solution set of $LCP(q, A)$ respectively. In this article, we introduce a class of matrices called semimonotone star matrix ($E^s_0$) by introducing the notion of star property to semimonotone matrix.

The outline of the article is as follows. In Section 2, some notations, definitions and results are presented that are used in the next sections. In section 3, we introduce semimonotone star ($E^s_0$)-matrix and study some properties of this class in connection with complementarity theory, principal pivot transform. Section 4 deals with PPT based matrix classes under $E^s_0$-property. In section 5, we consider the SOL($q, A$) under $E^s_0$-properties. In this connection we partially settle an open problem raised by Gowda and Jones [14]. We propose an iterative algorithm [8] to process $LCP(q, A)$ where $A \in E^s_0$, a subclass of $E^s_0$-matrix in section 6. Two numerical examples are presented to demonstrate the performance of the proposed algorithm in section 7.

## 2 Preliminaries

We denote the $n$ dimensional real space by $R^n$. $R^n_+$ and $R^n_{++}$ denote the nonnegative and positive orthant of $R^n$ respectively. We consider vectors and matrices with real entries. For any set $\beta \subseteq \{1, 2, \ldots, n\}$, $\bar{\beta}$ denotes its complement in $\{1, 2, \ldots, n\}$. Any vector $x \in R^n$ is a column vector unless otherwise specified and $x^T$ denotes the row transpose of $x$. For any matrix $A \in R^{n \times n}$, $a_{ij}$ denotes its $i$th row and $j$th column.
entry, \( A_j \) denotes the \( j \)th column and \( A_i \) denotes the \( i \)th row of \( A \). If \( A \) is a matrix of order \( n \), \( \emptyset \neq \alpha \subseteq \{1, 2, \ldots, n\} \) and \( \emptyset \neq \beta \subseteq \{1, 2, \ldots, n\} \) then \( A_{\alpha\beta} \) denotes the submatrix of \( A \) consisting of only the rows and columns of \( A \) whose indices are in \( \alpha \) and \( \beta \), respectively. For any set \( \alpha \), \( |\alpha| \) denotes its cardinality. \( \|A\| \) and \( \|q\| \) denote the norms of a matrix \( A \) and a vector \( q \) respectively.

The \emph{principal pivot transform} (PPT) of \( A \), a real \( n \times n \) matrix, with respect to \( \alpha \subseteq \{1, 2, \ldots, n\} \) is defined as the matrix given by

\[
M = \begin{bmatrix}
M_{\alpha\alpha} & M_{\alpha\bar{\alpha}} \\
M_{\bar{\alpha}\alpha} & M_{\bar{\alpha}\bar{\alpha}}
\end{bmatrix}
\]

where \( M_{\alpha\alpha} = (A_{\alpha\alpha})^{-1}, \ M_{\alpha\bar{\alpha}}=-(A_{\alpha\alpha})^{-1}A_{\alpha\bar{\alpha}}, \ M_{\bar{\alpha}\alpha} = A_{\bar{\alpha}\alpha}(A_{\alpha\alpha})^{-1}, \ M_{\bar{\alpha}\bar{\alpha}} = A_{\bar{\alpha}\bar{\alpha}} - A_{\bar{\alpha}\alpha}(A_{\alpha\alpha})^{-1}A_{\alpha\bar{\alpha}}. \) Note that PPT is only defined with respect to those \( \alpha \) for which \( \det A_{\alpha\alpha} \neq 0 \). By a legitimate principal pivot transform we mean the PPT obtained from \( A \) by performing a principal pivot on its nonsingular principal submatrices. When \( \alpha = \emptyset \), by convention \( \det A_{\alpha\alpha} = 1 \) and \( M = A \). For further details see [4], [6] and [19], [20] in this connection. The PPT of \( \text{LCP}(q, A) \) with respect to \( \alpha \) (obtained by pivoting on \( A_{\alpha\alpha} \)) is given by \( \text{LCP}(q', M) \) where \( M \) has the same structure already mentioned with \( q'_\alpha = -A_{\alpha\alpha}^{-1}q_\alpha \) and \( q'_\bar{\alpha} = q_\bar{\alpha} - A_{\bar{\alpha}\alpha}A_{\alpha\alpha}^{-1}q_\alpha \).

We say that \( A \in R^{n \times n} \) is

\begin{itemize}
  \item positive definite (PD) matrix if \( x^T A x > 0, \forall 0 \neq x \in R^n \).
  \item positive semidefinite (PSD) matrix if \( x^T A x \geq 0, \forall x \in R^n \).
  \item column sufficient matrix if \( x_i (Ax)_i \leq 0 \forall i \Rightarrow x_i (Ax)_i = 0 \forall i \).
  \item row sufficient matrix if \( A^T \) is column sufficient.
  \item sufficient matrix if \( A \) is both column and row sufficient.
  \item \( P(P_0) \)-matrix if all its principal minors are positive (nonnegative).
  \item \( N(N_0) \)-matrix if all its principal minors are negative (nonpositive).
  \item copositive \( (C_0) \) matrix if \( x^T A x \geq 0, \forall x \geq 0 \).
  \item strictly copositive \( (C) \) matrix if \( x^T A x > 0, \forall 0 \neq x \geq 0 \).
  \item copositive plus \( (C_0^+) \) matrix if \( A \) is copositive and \( x^T A x = 0, x \geq 0 \Rightarrow (A + A^T)x = 0 \).
  \item copositive star \( (C_0^*) \) matrix if \( A \) is copositive and \( x^T A x = 0, Ax \geq 0, x \geq 0 \Rightarrow A^T x \leq 0 \).
  \item semimonotone \( (E_0) \) matrix if for every \( 0 \neq x \geq 0, \exists \text{ an } i \text{ such that } x_i > 0 \text{ and } (Ax)_i \geq 0 \).
  \item \( L_2 \)-matrix if for every \( 0 \neq x \geq 0, x \in R^n, \text{ such that } Ax \geq 0, x^T A x = 0, \exists \text{ two diagonal matrices } D_1 \geq 0 \text{ and } D_2 \geq 0 \text{ such that } D_2 x \neq 0 \text{ and } (D_1 A + A^T D_2)x = 0 \).
  \item \( L \)-matrix if it is \( E_0 \cap L_2 \).
  \item strictly semimonotone \( (E) \) matrix if for every \( 0 \neq x \geq 0, \exists \text{ an } i \text{ such that } x_i > 0 \text{ and } (Ax)_i > 0 \).
  \item pseudomonotone matrix if for all \( x, y \geq 0, (y - x)^T A x \geq 0 \Rightarrow (y - x)^T A y \geq 0 \).
  \item positive subdefinite matrix \( (PSD) \) if \( \forall x \in R^n, x^T A x < 0 \Rightarrow \text{ either } A^T x \leq 0 \text{ or } A^T x \geq 0 \).
  \item fully copositive \( (C_0^*) \) matrix if every legitimate PPT of \( A \) is \( C_0 \)-matrix.
\end{itemize}
fully semimonotone\( (E_0^i)\) matrix if every legitimate PPT of \( A \) is \( E_0\)-matrix.

- almost \( P_0(P)\)-matrix if \( \det A_{\alpha} \geq 0 \) \( ( > 0 ) \) \( \forall \alpha \in \{1,2,\ldots,n\} \) and \( \det A < 0 \).

- an almost \( N_0(N)\)-matrix if \( \det A_{\alpha} \leq 0 \) \( ( < 0 ) \) \( \forall \alpha \in \{1,2,\ldots,n\} \) and \( \det A > 0 \).

- almost copositive matrix if it is copositive of order \( n-1 \) but not of order \( n \).

- almost \( E \)-matrix if it is \( E \) of order \( n-1 \) but not of order \( n \).

- almost fully copositive (almost \( C_0^i \)) matrix if its PPTs are either \( C_0 \) or almost \( C_0 \) and there exists at least one PPT \( M \) of \( A \) for some \( \alpha \in \{1,2,\ldots,n\} \) that is almost \( C_0 \).

- copositive of exact order \( k \) matrix if it is copositive up to order \( n-k \).

- \( Z \)-matrix if \( a_{ij} \leq 0 \).

- \( K_0\)-matrix \( [3] \) if it is \( Z \)-matrix as well as \( P_0\)-matrix.

- connected \( (E_c)\) matrix if \( \forall q \), \( \text{LCP}(q,A) \) has a connected solution set.

- \( R\)-matrix if \( \exists \) \( z \in R^n \), \( t(\geq 0) \in R \) satisfying

\[
A_i z + t = 0 \text{ if } i \text{ such that } z_i > 0,
\]

\[
A_i z + t \geq 0 \text{ if } i \text{ such that } z_i = 0.
\]

- \( R_0\)-matrix if \( \text{LCP}(0,A) \) has unique solution.

- \( Q_0\)-matrix if \( \text{SOL}(q,A) \) is nonempty and compact \( \forall q \in R^n \).

- \( Q\)-matrix if for every \( q \in R^n \), \( \text{LCP}(q,A) \) has a solution.

- \( Q_0\)-matrix if for any \( q \in R^n \), \( (1.1) \) has a solution implies that \( \text{LCP}(q,A) \) has a solution.

- completely \( Q\)-matrix \( (\bar{Q}) \) if all its principal submatrices are \( Q\)-matrices.

- completely \( Q_0\)-matrix \( (\bar{Q}_0) \) if all its principal submatrices are \( Q_0\)-matrices.

We state some game-theoretic results due to von Neumann \( [20] \) which are needed in the sequel. In a two person zero-sum matrix game, let \( v(A) \) denote the value of the game corresponding to the pay-off matrix \( A \). The value of the game \( v(A) \) is positive (nonnegative) if there exists a \( 0 \neq x \geq 0 \) such that \( Ax > 0 \) \( (Ax \geq 0) \). Similarly, \( v(A) \) is negative (nonpositive) if there exists a \( 0 \neq y \geq 0 \) such that \( A^T y < 0 \) \( (A^T y \leq 0) \).

The following result was proved by Văliahо \( [25] \) for symmetric almost copositive matrices. However this is true for nonsymmetric almost copositive matrices as well.

**Theorem 2.1.** \( [7] \) Let \( A \in R^{n \times n} \) be almost copositive. Then \( A \) is PSD of order \( n-1 \), and \( A \) is PD of order \( n-2 \).

**Theorem 2.2.** \( [10] \) Suppose \( A \in R^{n \times n} \) is a PSBD matrix and \( \text{rank}(A) \geq 2 \). Then \( A^T \) is PSBD and at least one of the following conditions hold:

(i) \( A \) is PSD matrix.

(ii) \( (A + A^T) \leq 0 \).

(iii) \( A \in C_0^* \).

**Theorem 2.3.** \( [10] \) Suppose \( A \in R^{n \times n} \) is a PSBD matrix and \( \text{rank}(A) \geq 2 \) and \( A + A^T \leq 0 \). If \( A \) is not a skew-symmetric matrix, then \( A \leq 0 \).

Here we consider some more results which will be required for next section. A matrix \( A \) is said to satisfy \((++)\)-property \( [3] \) if there exists a matrix \( X \in K_0 \) such that \( AX \) is a \( Z \)-matrix.
Theorem 2.4. Suppose \( A \in R^{n \times n} \) with \( A \) satisfies \((++)-\)property. If \( A \in E_0 \) then \( A \in P_0 \).

Theorem 2.5. Let \( A \in R^{n \times n} \) be given. Consider the statements

(i) \( A \in R \).
(ii) \( A \in \text{int}(Q) \cap R_0 \).
(iii) the zero vector is a stable solution of the LCP(0, \( A \)).
(iv) \( A \in Q \cap R_0 \).
(v) \( A \in R_0 \).

Then the following implications hold: (i) \( \Rightarrow \) (ii) \( \Rightarrow \) (iii) \( \Rightarrow \) (iv) \( \Rightarrow \) (v). Moreover, if \( A \in E_0 \), then all five statements are equivalent.

Theorem 2.6. Let \( A \in \text{int}(Q) \cap R_0 \). If the LCP(\( q, A \)) has a unique solution \( x^* \), then LCP(\( q, A \)) is stable at \( x^* \).

Theorem 2.7. Let \( A \in R^{n \times n} \) be such that for some index set \( \alpha \) (possibly empty), \( \bar{A}_\alpha = 0 \). If \( A_{\alpha\alpha} \in P_0 \cap Q \), then SOL(\( q, A \)) is connected for every \( q \).

Theorem 2.8. Suppose that \( A \) is pseudomonotone on \( R^n_+ \). Then \( A \) is a \( P_0 \)-matrix.

Theorem 2.9. Suppose that \( A \) is pseudomonotone on \( R^n_+ \). Then \( A \) is a \( P_0 \)-matrix.

Theorem 2.10. Suppose that \( A \in R^{n \times n} \cap E_c \). Then \( A \in E'_0 \).

Theorem 2.11. Any \( 2 \times 2 \) \( P_0 \)-matrix with positive diagonal is sufficient.

Theorem 2.12. \( L \)-matrices are \( Q_0 \)-matrices.

Theorem 2.13. Let \( A \in R^{n \times n} \) where \( n \geq 2 \). Then \( A \) is sufficient if and only if \( A \) and each of its principal pivot transforms are sufficient of order 2.

Theorem 2.14. Suppose \( A \in E_0 \cap R^{n \times n} \). If \( A \in R_0 \) then \( A \in Q \).

Theorem 2.15. \( Q_b = Q \cap R_0 \).

3 Some properties of \( E_0^s \)-matrices

We begin by the definition of semimonotone star \( (E_0^s) \) matrix.

Definition 3.1. A semimonotone matrix \( A \) is said to be semimonotone star \( (E_0^s) \) matrix if \( x^T A x = 0, A x \geq 0, x \geq 0 \implies A^T x \leq 0 \).

Example 3.1. Let us consider the matrix \( A = \begin{bmatrix} 0 & -5 \\ 2 & 0 \end{bmatrix} \). Now \( x^T A x = -3x_1x_2 \).

Consider \( x = \begin{bmatrix} k_1 \\ k_2 \end{bmatrix} \), where \( k_1, k_2 \geq 0 \). Hence we consider the following cases.

Case I: For \( k_1 = k_2 = 0, x = 0, A x = 0, x^T A x = 0 \) implies \( A^T x = 0 \).
Case II: For \( k_1 > 0, k_2 = 0, x \geq 0, A x \geq 0, x^T A x = 0 \) implies \( A^T x \leq 0 \).
Case III: For \( k_1 = 0, k_2 > 0, x \geq 0, x^T A x \geq 0 \). However \( x \not\geq 0 \).
Hence \( A \in E_0^s \).
The following result shows that $E_0^s$-matrices are invariant under principal rearrangement and scaling operations.

**Theorem 3.16.** If $A \in R^{n \times n} \cap E_0^s$-matrix and $P \in R^{n \times n}$ is any permutation matrix, then $PAP^T \in E_0^s$.

**Proof.** Let $A \in E_0^s$ and let $P \in R^{n \times n}$ be any permutation matrix. Then $PAP^T$ is an $E_0^s$-matrix by the Theorem 4.3 of [24]. Now for any $x \in R^n_+$ let $y = P^T x$. Note that $x^T PAP^T x = y^T A y = 0$, $A^T x = A y \geq 0 \Rightarrow A^T y = A^T P^T x \leq 0$, since $P$ is a permutation matrix. It follows that $PAP^T$ is a $E_0^s$-matrix. The converse of the above theorem follows from the fact that $P^T P = I$ and $A = P^T (PAP^T)(P^T)^T$. \qed

**Example 3.2.** Let $A = \begin{bmatrix} 0 & 1 & 1 \\ 2 & 0 & 2 \\ -4 & -5 & 0 \end{bmatrix}$. Clearly, $A \in E_0$. The nonzero vectors in $SOL(0, A)$ are of the form $x = \begin{bmatrix} 0 \\ 0 \\ k \end{bmatrix}$ for $k > 0$, and for such $x$ the inequality $A^T x \leq 0$ holds. Therefore $A \in E_0^s$. Consider $P = \begin{bmatrix} 0 & 0 & 1 \\ 1 & 0 & 0 \\ 0 & 1 & 0 \end{bmatrix}$. We get

$$PAP^T = \begin{bmatrix} 0 & -4 & -5 \\ 1 & 0 & 1 \\ 2 & 2 & 0 \end{bmatrix}. $$

Hence $x^T PAP^T x = 0$, $PAP^T x \geq 0$, $x \geq 0$ imply $P^T A^T P x \leq 0$. Therefore $PAP^T$ is a $E_0^s$-matrix.

**Theorem 3.17.** Suppose $A \in R^{n \times n}$ is a $E_0^s$-matrix. Let $D \in R^{n \times n}$ be a positive diagonal matrix. Then $A \in E_0^s$ if and only if $DAD^T \in E_0^s$.

**Proof.** Let $A \in E_0^s$. For any $x \in R^n_+$, let $y = D^T x$. Note that $x^T DAD^T x = y^T A y = 0$, $AD^T x = A y \geq 0 \Rightarrow A^T y = A^T D^T x \leq 0$ since $D$ is a positive diagonal matrix. Thus $DAD^T \in E_0^s$. The converse follows from the fact that $D^{-1}$ is a positive diagonal matrix and $A = D^{-1}(DAD^T)(D^{-1})^T$. \qed

The following example shows that $A \in E_0^s$-matrix does not imply $(A + A^T) \in E_0^s$-matrix.

**Example 3.3.** Let $A = \begin{bmatrix} 0 & 1 & 1 \\ 2 & 0 & 1 \\ -1 & -1 & 0 \end{bmatrix}$. Clearly $A \in E_0^s$, since $x^T A x = 0$, $Ax \geq 0$, $x \geq 0$ imply $A^T x \leq 0$.

It is easy to show that $A + A^T = \begin{bmatrix} 0 & 3 & 0 \\ 3 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}$ is not an $E_0^s$-matrix.

We show that PPT of $E_0^s$-matrix need not be $E_0^s$-matrix.
Example 3.4. Let us consider the matrix $A = \begin{bmatrix} 0 & 1 & 1 \\ 2 & 0 & 1 \\ -1 & -1 & 0 \end{bmatrix}$. Note that $A \in E_0^s$ but it is easy to show that $A^{-1} = \frac{1}{3} \begin{bmatrix} -1 & 1 & -1 \\ 1 & -1 & -2 \\ 2 & 1 & 2 \end{bmatrix}$ is not a $E_0^s$-matrix. Therefore any PPT of $E_0^s$-matrix need not be $E_0^s$-matrix.

Note that a matrix is in $E_0^s$ if and only if its transpose is in $E_0^s$. We show that $A \in E_0^s$-matrix does not imply $A^T \in E_0^s$-matrix in general.

Example 3.5. Let us consider the matrix $A = \begin{bmatrix} 0 & 1 & 1 \\ 2 & 0 & 1 \\ -1 & -1 & 0 \end{bmatrix}$. Note that $A \in E_0^s$ but it is easy to show that $A^T = \begin{bmatrix} 0 & 2 & -1 \\ 1 & 0 & -1 \\ -1 & 1 & 0 \end{bmatrix}$ is not a $E_0^s$-matrix.

Now we show a condition under which $A^T$ satisfies $E_0^s$-property.

Theorem 3.18. Suppose that $A$ is pseudomonotone on $R_+^n$ and $A^T \in R_0$. Then $A^T$ satisfies $E_0^s$-property.

Proof. Since $A$ is pseudomonotone on $R_+^n$, then $A$ is $P_0$ matrix by Theorem 2.9. Hence $A \in E_0$. We have to show that $A^T$ satisfies the following property.

$$0 \neq x \geq 0, \ A^T x \geq 0, \text{ and } x^T A^T x = 0 \implies A x \leq 0.$$  

For rest of the proof, we apply the approach given by [11]. Since $A^T \in R_0$ then $0 \neq x \geq 0, \ A^T x = 0$ has no solution then for at least for one $i$, $(A^T x)_i > 0$. Let us define $e_i$ be the vector which has one at the $i$-th portion and zeros elsewhere. Now consider $y = e_i + \lambda e_j$, where $i \neq j$ and $\lambda \geq 0$. Then, for any small $\delta > 0$, we get

$$(x - \delta y)^T A (\delta y) = \delta [(A^T x)_i + \lambda (A^T x)_j - \delta y^T A y] \geq 0.$$  

By pseudomonotonicity, $(x - \delta y)^T A x \geq 0$. Thus $y^T A x \leq 0$. This gives $(A x)_i + \lambda (A x)_j \leq 0$. As $\delta$ is arbitrary, $(A x)_i \leq 0$ and $(A x)_j \leq 0$. Hence $A x \leq 0$. \hfill \Box

Corollary 3.1. Suppose that $A$ is pseudomonotone on $R_+^n$, and satisfies one of the following conditions:

(i) $A$ is invertible.

(ii) $A$ is normal i.e. $A A^T = A^T A$.

Then $A^T \in E_0^s$.

Note that $C_0^s \subseteq E_0^s$.

Definition 3.2. A matrix $A$ is said to be completely semimonotone star ($E_0^s$) matrix if all its principal submatrices are semimonotone star matrix.
We say that $E_0^s$ is not a complete class which can be illustrated with the following example.

**Example 3.6.** Let us consider the matrix $A = \begin{bmatrix} 0 & 1 & 1 \\ 2 & 0 & 1 \\ -4 & -5 & 0 \end{bmatrix}$. Note that $A \in E_0^s$ but it is easy to show that $A_{12} = \begin{bmatrix} 0 & 1 \\ 2 & 0 \end{bmatrix}$ is not a $E_0^s$-matrix.

**Theorem 3.19.** Let $A \in \text{PSBD} \cap E_0$ with rank($A$) $\geq 2$. Further suppose $A$ is not a skew symmetric matrix. Then $A \in E_0^s$-matrix.

**Proof.** Let $A$ be PSBD matrix with rank($A$) $\geq 2$. By the Theorem 2.2 we have following three cases.

Case I: $A$ is PSD matrix. This implies $A \in E_0^s$. 

Case II: $A \in C_0^s$. This implies $A \in E_0^s$.

Case III: $(A + A^T) \leq 0$. As $A$ is a PSBD matrix with rank($A$) $\geq 2$, $A \leq 0$ by the Theorem 2.3. Note that $A \in E_0$. To show $A \in E_0^s$, consider $x^T Ax = 0$, $Ax \geq 0$, $x \geq 0$. Now this implies $A^T x \leq 0$. Hence $A \in E_0^s$. \qed

**Example 3.7.** Let us consider the matrix $A = \begin{bmatrix} 0 & 3 \\ -1 & 0 \end{bmatrix}$. It is easy to show that $A$ is PSBD matrix with rank($A$) $\geq 2$. Hence by Theorem 3.19, $A \in E_0^s$.

### 4 PPT based matrix classes under $E_0^s$-property

Some of the PPT based matrix classes are defined in the context of linear complementarity problem. Here we consider some PPT based matrix classes with $E_0^s$-property in the context of linear complementarity problem to show that these classes are processable by Lemke’s algorithm under certain condition. We settle the processability of Lemke’s algorithm through identification of new subclass of $P_0 \cap Q_0$-matrices.

**Definition 4.3.** A matrix $A \in E_0^s$ is said to be $\tilde{E}_0^s$-matrix if for $x \in SOL(0, A)$, $(A^T x)_i \neq 0 \implies (Ax)_i \neq 0 \ \forall \ i$.

**Example 4.8.** Let us consider $A = \begin{bmatrix} 0 & 1 & 1 \\ 2 & 0 & 2 \\ -2 & -4 & 0 \end{bmatrix}$. Note that, $A \notin C_0^s$. For $k > 0$

and $x = \begin{bmatrix} 0 \\ 0 \\ k \end{bmatrix}$, $x \geq 0$, $Ax \geq 0$, $x^T Ax = 0$ implies $A^T x \leq 0$. Hence $A \in E_0^s$. Now

$A^T x = \begin{bmatrix} 0 \\ 0 \\ -2 \\ -4 \\ 0 \end{bmatrix}$ and $Ax = \begin{bmatrix} 1 \\ 2 \\ 0 \end{bmatrix}$. Therefore $\forall \ i$, $(A^T x)_i \neq 0 \implies (Ax)_i \neq 0$. Hence $A \in \tilde{E}_0^s$.

**Remark 4.1.** It is easy to show that $C_0^s \subseteq \tilde{E}_0^s$.
Note that not every $E_0^s$-matrix is $\tilde{E}_0^s$-matrix. We consider the following example from the paper [13].

**Example 4.9.** Consider $A = \begin{bmatrix} 1 & -1 & -2 \\ -1 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}$. Note that $A \in P_0$. Hence $A \in E_0$.

The only nonzero vectors in $SOL(0, A)$ are of the form $x = \begin{bmatrix} k \\ -k \\ 0 \end{bmatrix}$ for $k > 0$. Now for such $x$, $A^T x \leq 0$ holds. Hence $A \in E_0^s$. Now $A^T x = \begin{bmatrix} 0 \\ 0 \\ -2k \end{bmatrix}$ and $Ax = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$.

Note that $(A^T x)_3 \neq 0$ but $(Ax)_3 = 0$. Hence $A \notin \tilde{E}_0^s$.

**Theorem 4.20.** Let $A \in R^{n \times n} \cap \tilde{E}_0^s$. Assume that every legitimate PPT of $A$ is either almost $E$ or completely $\tilde{E}_0^s$. Then $A \in P_0$.

**Proof.** Since $A \in \tilde{E}_0^s$, we write $x \in SOL(0, A)$ implies $A^T x \leq 0$ and $(A^T x)_i \neq 0 \implies (Ax)_i \neq 0 \forall i$. Now by taking $D_2 = I$, where $I$ represents the identity matrix. Then $D_2 x = Ix \neq 0$. So $(D_1 A + A^T I) x = 0$ by taking,

$$D_{ii} = \begin{cases} -\frac{(A^T x)_i}{(Ax)_i}, & (Ax)_i \neq 0, \\ 0, & (Ax)_i = 0. \end{cases}$$

Where $D_{ii}$ denotes the $i$th diagonal of $D_1$. So $A \in E_0^s \cap L_2$. Therefore $A \in Q_0$ by the Theorem 2.12. For rest of the proof, we follow the approach given by Das [7]. However for the sake of completeness we give the proof. Note that every legitimate PPT of $A$ is either almost $E$ or completely $\tilde{E}_0^s$. Suppose $M$ is a PPT of $A$ so that $M \in \text{almost } E$. Then all principal submatrices of $M$ upto $n - 1$ order are $\tilde{Q}$. Hence $M \in Q_0$. Since the PPT of $A$ is either almost $E$ or completely $\tilde{E}_0^s$, it follows that all proper principal submatrices are $P_0$.

Now to complete the proof, we need to show that $\det A \geq 0$. Suppose not. Then $\det A < 0$. This implies that $A$ is an almost $P_0$-matrix. Therefore $A^{-1} \in N_0$. If $A^{-1} \in \text{almost } E$ then this contradicts that the diagonal entries are positive. Therefore $\det A \geq 0$. It follows that $A \in P_0$.

**Corollary 4.2.** Let $A \in R^{n \times n} \cap \tilde{E}_0^s$. Assume that every legitimate PPT of $A$ is either almost $E$ or completely $\tilde{E}_0^s$. Then $\text{LCP}(q, A)$ is processable by Lemke’s algorithm.

Earlier Das [7] proposed exact order 2 $C_0^f$-matrices in connection with PPT based matrix classes. We define exact order $k$ $C_0^f$-matrices.
Definition 4.4. A is said to be an exact order \( k \) \( C_0^f \)-matrix if its PPTs are either exact order \( k \) \( C_0 \) or \( E_0 \) and there exists at least one PPT \( M \) of \( A \) for some \( \alpha \subset \{1, 2, \cdots, n\} \) that is exact order \( k \) \( C_0 \).

We prove the following theorem.

Theorem 4.21. Let \( A \in \tilde{E}_0^s \cap \text{exact order } k \ C_0^f \ (n \geq k + 2) \). Assume that PPT of \( A \) has either exact order \( k \) \( C_0 \) or \( E_0 \) with at least \( k \) positive diagonal entries. Then \( \text{LCP}(q, A) \) is processable by Lemke’s algorithm.

Proof. We show that \( A \in P_0 \). Suppose \( M \) is a PPT of \( A \) so that \( M \in \text{exact order } k \ C_0 \). By Theorem 2.1, all the principal submatrices of order \((n - k)\) of \( M \) are PSD. Now to show \( M^{(n-k+1)} \in P_0 \) it is enough to show that \( \det M^{(n-k+1)} \geq 0 \). Suppose not. Then \( \det M^{(n-k+1)} < 0 \). We consider \( B = M^{(n-k+1)} \) is an almost \( C_0 \)-matrix. Therefore \( B^{-1} \in N_0 \) and there exists a nonempty subset \( \alpha \subset \{1, 2, \ldots, n-1\} \) satisfying

\[
B_{aa}^{-1} \leq 0, \ B_{aa}^{-1} \leq 0, \ B_{aa}^{-1} \geq 0 \text{ and } B_{aa}^{-1} \geq 0.
\]

(4.1)

By definition \( B^{-1} \in E_0 \) with at least \( k \) positive diagonal entry. This contradicts Equation 4.1. Therefore \( \det M^{(n-k+1)} \geq 0 \). Now by the same argument as above, we show that \( \det M \geq 0 \). Therefore it follows that \( A \in P_0 \). Hence \( A \in P_0 \cap \tilde{E}_0^s \). So \( \text{LCP}(q, A) \) is processable by Lemke’s Algorithm.

Now we establish the condition under which a matrix \( A \) is sufficient satisfying \((++)\)-property.

Theorem 4.22. Suppose \( A \in R^{n \times n} \cap E_0 \) satisfies \((++)\)-property. If each legitimate PPT of \( A \) are either almost \( C_0 \) or completely \( \tilde{E}_0^s \) with full rank second order principal submatrices, then \( A \) is sufficient.

Proof. As \( A \in E_0 \) with \((++)\)-property. Hence \( A \in P_0 \) by Theorem 2.4. Suppose \( M \) be a PPT of \( A \). We consider the following cases.

Case I: If \( M \) be almost \( C_0 \), then by the Theorem 2.1, \( M \) is PSD of order \((n - 1)\). Hence \( M \) is PSD of order 2 also. So by the Theorem 2.13, \( M \) is sufficient of order \((n - 1)\).

Case II: If \( M \) is completely \( \tilde{E}_0^s \) then sign pattern of all 2 \( \times \) 2 submatrices of \( M \) will be in the following subcases:

Subcase I: If the sign pattern is \[
\begin{bmatrix}
0 & + \\
- & 0
\end{bmatrix}
or
\begin{bmatrix}
0 & - \\
+ & 0
\end{bmatrix}
\] then these two patterns are sufficient.

Subcase II: If the sign pattern is \[
\begin{bmatrix}
+ & + \\
- & +
\end{bmatrix}
or
\begin{bmatrix}
+ & - \\
+ & +
\end{bmatrix}
\] then by the Theorem 2.11 these two patterns are sufficient.

Subcase III: If the sign pattern is \[
\begin{bmatrix}
+ & + \\
+ & +
\end{bmatrix}
\] then by the Theorem 2.11 this pattern is sufficient.

Subcase IV: If the sign pattern is \[
\begin{bmatrix}
+ & - \\
- & +
\end{bmatrix}
\] then by the Theorem 2.11 this pattern...
is sufficient. Then for every PPT, $A_{aa}$ of order 2 are sufficient. By the Theorem 5.23 $A$ is sufficient.

5 Properties of SOL($q, A$) under $E_0^s$-property

We show that solution set of LCP($q, A$) is connected if $A \in E_0^s$ with the following structure $A = \begin{bmatrix} A_{aa} & + \\ - & 0 \end{bmatrix}$, where $A_{aa} \in R^{(n-1)\times(n-1)}$.

**Theorem 5.23.** Let $A \in R^{n \times n}$ with $A = \begin{bmatrix} A_{aa} & + \\ - & 0 \end{bmatrix}$ and $A_{aa} \in P_0$. Then $A \in E_0^s$-matrix.

**Proof.** First we show that $A = \begin{bmatrix} A_{aa} & + \\ - & 0 \end{bmatrix}$ with $A_{aa} \in P_0$ is $E_0$-matrix. Let us consider $(u_\alpha, v) \in R^s_0$ be a given vector where $\alpha = \{1, 2, \ldots, (n-1)\}$. Without loss of generality we assume $u_\alpha \neq 0$. Now as $A_{aa} \in P_0$, we can write $A_{aa} \in E_0$. By semimonotonicity $A_{aa} \exists$ an index $i$ such that $(u_\alpha)_i > 0$ and $(A_{aa} u_\alpha)_i \geq 0$. For such an index $i$, $(A_{aa} u_\alpha + v)_i \geq 0$. Hence $A \in E_0$. We consider the following two cases:

Case I: First we take $x = [x_\alpha, 0]^T$, where $\alpha = \{1, 2, \ldots, (n-1)\}$. Then suppose $x^T A x = 0$, $x \geq 0$, but in this case $Ax \not\geq 0$.

Case II: Take $x = [x_\alpha, x_\alpha]^T$, where $x_\alpha, x_\alpha \geq 0$. Then suppose for this $x$, $x^T A x = 0$, but $Ax \not\geq 0$. So the vector $x$ for which $x^T A x = 0$, $Ax \geq 0$, $x \geq 0$, are the zero vector and $[0, 0, \ldots, c]^T, c > 0$ and for both cases $A^T x \leq 0$.

Hence $A$ is $E_0^s$ matrix. Now it is easy to show that for $x = [0, 0, \ldots, c]^T$, $(A^T x)_i \neq 0$ implies $(Ax)_i \not\geq 0$ for each $i$. Hence $A \in E_0^s$.

**Theorem 5.24.** Suppose $A \in R^{n \times n}$ with $A = \begin{bmatrix} A_{aa} & + \\ - & 0 \end{bmatrix}$ and $A_{aa} \in P_0 \cap Q$. Then $A$ is connected matrix i.e. $A \in E_c$.

**Proof.** Result follows from the Theorem 2.7 of [22].

**Remark 5.2.** Suppose $A \in R^{n \times n}$ with $A = \begin{bmatrix} A_{aa} & + \\ - & 0 \end{bmatrix}$ and $A_{aa} \in P_0 \cap Q$. Now as $A \in E_c$ so $A \in E_c \cap Q_0$ and by the Theorem 2.8 Lemke’s algorithm processes LCP($q, A$).

**Theorem 5.25.** Suppose that $A \in R^{n \times n}$ with $A = \begin{bmatrix} A_{aa} & + \\ - & 0 \end{bmatrix}$ and $A_{aa} \in P_0 \cap Q$. Then $A \in P_0$.

**Proof.** Since $A \in R^{n \times n}$ with $A = \begin{bmatrix} A_{aa} & + \\ - & 0 \end{bmatrix}$ and $A_{aa} \in P_0 \cap Q$ then by the Theorem 5.24 $A \in E_c$. Again by the Theorem 2.10 $A \in E_0^f$. As $A \in E_0^s$ by the Theorem 5.23 $A \in L$ by the Theorem 4.20. By applying degree theory, $A \in P_0$ in view of Corollary 3.1 of [17].
Remark 5.3. Gowda and Jones [14] raised the following open problem: Is it true that \( P_0 \cap Q_0 = E_c \cap Q_0 \)? Cao and Ferris [2] showed that \( P_0 \cap Q_0 = E_c \cap Q_0 \) is true for second order matrices. We settle the above open problem partially by considering a subclass \( P_0 \cap \tilde{E}_0^s \) of \( P_0 \cap Q_0 \).

In general, SOL\((q, A)\) is not bounded for every \( q \in \text{int pos}[-A, I] \) and \( A \in \tilde{E}_0^s \). Here we establish the following results.

**Theorem 5.26.** Let \( A \in \tilde{E}_0^s \) and SOL\((q, A)\) is not bounded for all \( q \in \text{int pos}[-A, I] \). Suppose \( r \in K(A) \) and \( \exists \) vectors \( z \) and \( z^\lambda = \hat{z} + \lambda z \) such that \( z \in \text{SOL}(0, A) \setminus \{0\} \), \( z^\lambda \in \text{SOL}(q, A) \ \forall \lambda \geq 0 \) and \( w \in \text{SOL}(r, A) \). Then \((z^\lambda - w)_\alpha(A(z^\lambda - w))_\alpha < 0 \ \forall \alpha = \{i : z_i \neq 0\} \).

**Proof.** Suppose \( A \in \tilde{E}_0^s \) and SOL\((q, A)\) is not bounded for all \( q \in \text{int pos}[-A, I] \). Note that \( A \in E_0^s \cap L_2 \) as shown in Theorem 4.20 and \( q \in \text{int pos}[-A, I] \) and there exist vectors \( z \) and \( z^\lambda = \hat{z} + \lambda z \) such that \( z \in \text{SOL}(0, A) \setminus \{0\} \) and \( z^\lambda \in \text{SOL}(q, A) \ \forall \lambda \geq 0 \). We select an \( r \in K(A) \) such a way that \( \alpha = \{i : z_i \neq 0\} \). Then \( r_i - q_i < 0 \) Now for sufficiently large \( \lambda \), \((z^\lambda - w)_\alpha > 0 \) and \( w \in \text{SOL}(r, A) \). We write
\[
(A(z^\lambda - w))_\alpha = -q_\alpha - (Aw)_\alpha \leq -q_\alpha + r_\alpha < 0.
\]
This implies
\[
(z^\lambda - w)_\alpha(A(z^\lambda - w))_\alpha < 0.
\]
However strict inequality does not hold in case of \( \alpha \neq \{i : z_i \neq 0\} \).

**Theorem 5.27.** Let \( A \in \tilde{E}_0^s \) and SOL\((q, A)\) is not bounded for all \( q \in \text{int pos}[-A, I] \). Suppose \( r \in K(A) \) and \( \exists \) vectors \( z \) and \( z^\lambda = \hat{z} + \lambda z \) such that \( z \in \text{SOL}(0, A) \setminus \{0\} \), \( z^\lambda \in \text{SOL}(q, A) \ \forall \lambda \geq 0 \) and \( \hat{z} \in \text{SOL}(r, A) \). Then \((z^\lambda - w)_\alpha(A(z^\lambda - w))_\alpha \leq 0 \ \forall \alpha = \{i : \hat{z}_i \geq 0, z_i = 0\} \).

**Proof.** The first part of the proof follows from the proof of Theorem 5.26. Now we select an \( r \in K(A) \) and consider \( \alpha = \{i : z_i \neq 0\} \). We select an \( r \in K(A) \) and consider \( \alpha = \{i : z_i = 0\} \). Then \( r_i - q_i \geq 0 \). Now for sufficiently large \( \lambda \), \((z^\lambda - w)_\alpha > 0 \) and \( w \in \text{SOL}(r, A) \). To prove this we consider following two cases.

Case I: Let \( \alpha = \{i : \hat{z}_i > 0, z_i = 0\} \). Then \( r_i - q_i = 0 \). We write
\[
(z^\lambda - w)_i(A(z^\lambda - w))_i = (z^\lambda - w)_i((Az^\lambda)_i - (Aw)_i + q_i - r_i) = z^\lambda_i((Az^\lambda)_i + q_i) - w_i((Az^\lambda)_i + q_i) - z^\lambda_i(-Aw)_i - w_i(-Aw)_i - r_i \leq 0.
\]

Case II: Let \( \alpha = \{i : z_i = \hat{z}_i = 0\} \). Then \( r_i - q_i > 0 \). We write
\[
(z^\lambda - w)_i(A(z^\lambda - w))_i = -w_i((Az^\lambda)_i - (Aw)_i) \leq -w_i((Az^\lambda)_i - (Aw)_i + q_i - r_i) = -w_i(Az^\lambda + q)_i + w_i(Aw + r)_i = -w_i(Az^\lambda + q)_i \leq 0.
\]
Now we show the condition for which SOL(q,A) is compact where $A \in \bar{E}_0^s$. To establish the result we use game theoretic approach and Ville’s theorem of alternative.

**Theorem 5.28.** Suppose $A \in \bar{E}_0^s$ with $v(A) > 0$. Then SOL(q,A) is compact.

**Proof.** By theorem 4.20, $\bar{E}_0^s \subseteq E_0 \cap L_2$. Since $v(A) > 0$, So $A \in E_0^s \cap Q$. Now we consider $A \in R_0$, it is enough to show that LCP(0,A) has only trivial solution. Suppose not, then LCP(0,A) has nontrivial solution, i.e. say, $0 \neq x \in SOL(0,A)$ then $0 \neq x \geq 0$, $Ax \geq 0$ and $x^TAx = 0$. Since $A \in E_0^s$, we can write $A^Tx \leq 0$. Now $A^Tx \leq 0$, $0 \neq x \geq 0$ has a solution. According to Ville’s theorem of alternative, there does not exist $x > 0$ such that $Ax > 0$. However, $Ax > 0$, $x > 0$ has a solution since $A \in Q$. This is a contradiction. Hence LCP(0,A) has only trivial solution. Therefore $A \in Q \cap R_0$. Now by the Theorem 2.15, $A \in Q_0$. Hence SOL(q,A) is nonempty and compact.

We illustrate the result with the help of an example.

**Example 5.10.** Let us consider the matrix $A = \begin{bmatrix} 0 & 2 & 1 \\ 1 & 0 & 1 \\ -2 & -2 & 1 \end{bmatrix}$. Now $x^TAx = 3x_1x_2 + x_3^2 - x_3(x_1 + x_2)$. Now we consider the following four cases.

**Case I:** For $x_1 = 0$, $x_2 = k$, $x_3 = 0$, where $k > 0$. Here $x \geq 0$, $x^TAx = 0$ holds but in this case $Ax \not\geq 0$.

**Case II:** For $x_1 = k$, $x_2 = 0$, $x_3 = 0$, where $k > 0$. Here $x \geq 0$, $x^TAx = 0$ holds but in this case $Ax \not\geq 0$.

**Case III:** $x_1 = 0$, $x_2 = k$, $x_3 = k$, where $k > 0$. Here $x \geq 0$, $x^TAx = 0$ holds but in this case $Ax \not\geq 0$.

**Case IV:** $x_1 = k$, $x_2 = 0$, $x_3 = k$, where $k > 0$. Here $x \geq 0$, $x^TAx = 0$ holds but in this case $Ax \not\geq 0$.

Hence zero vector is the only vector for which $x \geq 0$, $Ax \geq 0$, $x^TAx = 0$ implies $A^Tx \leq 0$ holds. So $A \in E_0^s$-matrix. Also it is clear that $A \in \bar{E}_0^s$. Here we get that LCP(0,A) has unique solution. Hence $A \in R_0$.

We state some notion of stability of a linear complementarity problem at a solution point.

**Definition 5.5.** A solution $x^*$ is said to be stable if there are neighborhoods $V$ of $x^*$ and $U$ of $(q,A)$ such that

(i) for all $(\bar{q}, \bar{A}) \in U$, the set SOL($\bar{q}, \bar{A}$) $\cap V \neq \emptyset$.

(ii) sup$\{\|y - x^*\| : y \in$ SOL($\bar{q}, \bar{A}$) $\cap V \neq \emptyset\}$ goes to 0 as $(\bar{q}, \bar{A})$ approaches $(q,A)$.

**Definition 5.6.** A solution $x^*$ is said to be strongly stable if there exists a neighborhood $V$ of $x^*$ such that the set SOL($\bar{q}, \bar{A}$) $\cap V$ is singleton.

**Definition 5.7.** A solution $x^*$ is said to be locally unique if there exists a neighborhood $V$ of $x^*$ such that SOL($\bar{q}, \bar{A}$) $\cap V = \{x^*\}$.
The following result shows that the solution set of $LCP(q, A)$ is stable when $A \in \tilde{E}_0^s$.

**Theorem 5.29.** Suppose $A \in \tilde{E}_0^s$ with $v(A) > 0$, if the $LCP(q, A)$ has unique solution $x^*$, then $LCP(q, A)$ is stable at $x^*$.

**Proof.** As $A \in \tilde{E}_0^s$ with $v(A) > 0$, then by the Theorem 5.28, $A \in R_0^0$. Again as shown in the Theorem 2.5, $A \in \text{int}(Q) \cap R_0^0$. So by the Theorem 2.6 if the $LCP(q, A)$ has unique solution $x^*$, then $LCP(q, A)$ is stable at $x^*$.

\[ \square \]

### 6 Iterative algorithm to process $LCP(q, A)$

Aganagic and Cottle [1] proved that Lemke’s algorithm processes $LCP(q, A)$ if $A \in P_0 \cap Q_0$. Todd and Ye [23] proposed a projective algorithm to solve linear programming problem considering a suitable merit function. Using the same merit function Pang [21] proposed an iterative descent type algorithm with a fixed value of the parameter value $\kappa$ to process $LCP(q, A)$ where $A$ is a row sufficient matrix. Kojima et al. [15] proposed an interior point method to process $P_0$-matrices using similar type of merit function. Here we propose a modified version of interior point algorithm by using a dynamic $\kappa$ for each iterations in line with Pang [21] for finding solution of $LCP(q, A)$ given that $A \in \tilde{E}_0^s$. Note that $\tilde{E}_0^s$ contains $P_0$-matrices as well as non $P_0$-matrices. We prove that the search directions generated by the algorithm are descent and show that the proposed algorithm converges to the solution under some defined conditions.

**Algorithm.**

Let $z > 0$, $w = q + Az > 0$, and $\psi : R_+^n \times R_+^n \to R$ such that $\psi(z, w) = \kappa \log(z^T w) - \sum_{i=1}^n \log(z_i w_i) \geq 0$. Further suppose $\rho_k = \min_i \{z_i w_i\}$ and $\kappa_k > \max(n, \frac{\rho_k}{\rho_k})$ for $k$-th iteration.

**Step 1:** Let $\beta \in (0, 1)$ and $\sigma \in (0, \frac{1}{2})$ following line search step and $z^0$ be a strictly feasible point of $LCP(q, A)$ and $w^0 = q + Az^0 > 0$.

$$
\nabla_z \psi_k = \nabla_z \psi(z^k, w^k), \quad \nabla_w \psi_k = \nabla_w \psi(z^k, w^k)
$$

and

$$
Z^k = \text{diag}(z^k), \quad W^k = \text{diag}(w^k).
$$

**Step 2:** Now to find the search direction, consider the following problem

$$
\text{minimize} \quad (\nabla_z \psi_k)^T d_z + (\nabla_w \psi_k)^T d_w
$$

subject to $d_w = Ad_z$, $\| (Z^k)^{-1} d_z \|^2 + \| (W^k)^{-1} d_w \|^2 \leq \beta^2$.

**Step 3:** Find the smallest $m_k \geq 0$ such that
\[\psi(z^k + 2^{-m_k}d_z^k, w^k + 2^{-m_k}d_w^k) - \psi(z^k, w^k) \leq \sigma 2^{-m_k}[(\nabla_{z}\psi)T d_z^k + (\nabla_{w}\psi)T d_w^k].\]

**Step 4:** Set \((z^{k+1}, w^{k+1}) = (z^k, w^k) + 2^{-m_k}(d_z^k, d_w^k)\).

**Step 5:** If \((z^{k+1})^Tw^{k+1} \leq \epsilon\), where \(\epsilon\) is a very small positive quantity, stop else \(k = k + 1\).

**Remark 6.4.** The algorithm is based on the existence of strictly feasible point. As \(A \in \tilde{E}_0^s\) implies \(A \in Q_0\) in view of Theorem 6.20 then existence of strictly feasible points for such a matrix will eventually lead to the solution of LCP(q, A).

Now we prove the following lemma for \(E_0\)-matrices.

**Lemma 6.1.** Suppose \(A \in E_0\), \(z > 0\), \(w = q + Az > 0\), and \(\psi : R_{++}^n \times R_{++}^n \rightarrow R\) such that \(\psi(z, w) = \kappa \log(z^Tw) - \sum_{i=1}^{n} \log(z_iw_i)\). Further suppose \(\rho^k = \min_i \{z_iw_i^k\}\) and \(k^i > \max(n, \frac{z^Tw}{\rho^k})\) for each \(k\)th iteration. Then the search direction \((d_z^k, d_w^k)\) generated by the algorithm is descent direction.

**Proof.** Let us consider \(r^k = \nabla_{z}\psi^k + AT
abla_{w}\psi^k\) and first we show that \(r^k \neq 0\) for \(k\)th iteration. Let us consider the merit function \(z > 0\), \(w = q + Az > 0\) and \(\psi : R_{++}^n \times R_{++}^n \rightarrow R\) such that \(\psi(z, w) = \kappa \log(z^Tw) - \sum_{i=1}^{n} \log(z_iw_i) \geq 0\). Note that

\[
\left(\nabla_{z}\psi(z, w)\right)_i = \frac{\kappa}{z_iw_i}v_i - \frac{1}{z_iw_i}w_i = w_i\left[\frac{\kappa}{z_iw_i} - \frac{1}{z_iw_i}\right].
\]

Similarly we show

\[
\left(\nabla_{w}\psi(z, w)\right)_i = z_i\left[\frac{\kappa}{z_iw_i} - \frac{1}{z_iw_i}\right].
\]

Again for \(k\)th iteration \(\kappa^i > \max(n, \frac{z^Tw}{\rho^k})\) where \(\rho^k = \min_i \{z_iw_i^k\}\). This implies

\[z_i\left[\frac{\kappa}{z_iw_i} - \frac{1}{z_iw_i}\right] > 0.
\]

Therefore \(\left(\nabla_{w}\psi(z, w)\right)_i > 0\) \(\forall i\). In a similar way we can show that \(\left(\nabla_{z}\psi(z, w)\right)_i > 0\) \(\forall i\). Now \(A \in E_0\). So \(A^T \in E_0\). By the definition of semimonotonicity for \(\left(\nabla_{w}\psi(z, w)\right)_i > 0 \exists a j\) such that \((AT\nabla_{w}\psi(z, w))_j \geq 0\). Therefore \(\left(\nabla_{z}\psi(z, w)\right)_j + (AT\nabla_{w}\psi(z, w))_j \neq 0\) for at least one \(j\). Hence \(\nabla_{z}\psi(z, w) + AT\nabla_{w}\psi(z, w) \neq 0\). We have \(d_z^k = \frac{(A^k)^{-1}r^k}{\tau_k}\), \(d_w^k = Ad_z^k\) from the algorithm. Again \(A^k = (Z^k)^{-2} + AT(W^k)^{-2}A\) is positive definite as

\[x^TA^T(W)^{-2}Ax = (Ax)^T(W)^{-2}Ax = (y)^T(W)^{-2}y \geq 0, \forall y \in R^n, \ A^T(W)^{-2}A\text{ is positive semidefinite.} \]

So \(\tau_k = \frac{\sqrt{(r^k)^T(A^k)^{-1}r^k}}{\beta}\) is positive. Now we show that \(\nabla_{z}\psi^kT d_z^k + (\nabla_{w}\psi^k)T d_w^k < 0\). We derive

\[
\left(\nabla_{z}\psi^k\right)^T d_z^k + \left(\nabla_{w}\psi^k\right)^T d_w^k = \left[\nabla_{z}\psi^k + AT\nabla_{w}\psi^k\right]^T d_w^k = -\frac{1}{\tau_k} \sqrt{(r^k)^T(A^k)^{-1}r^k}^2 = -\tau_k\beta^2 < 0.
\]
Now we consider \( \psi(z^k + 2^{-m_k}d_z^k, w^k + 2^{-m_k}d_w^k) - \psi(z^k, w^k) \leq \sigma 2^{-m_k}[(\nabla_z \psi_k)^T d_z^k + (\nabla_w \psi_k)^T d_w^k] \). Since \( 0 < \beta, \sigma < 1 \), we say \( \psi(z^k + 2^{-m_k}d_z^k, w^k + 2^{-m_k}d_w^k) - \psi(z^k, w^k) < 0 \). Hence \( (d_z^k, d_w^k) \) is descent direction in this algorithm. \( \square \)

**Remark 6.5.** Note that the Lemma 6.1 is true for \( \tilde{E}_0^s \)-matrices as \( \tilde{E}_0^s \subseteq E_0 \).

We prove the following theorem to show that the proposed algorithm converges to the solution under some defined condition.

**Theorem 6.30.** If \( A \in \tilde{E}_0^s \) and LCP\((q,A)\) has a strictly feasible solution, then every accumulation point of \( \{z^k\} \) is the solution of LCP\((q,A)\) i.e. algorithm converges to the solution.

**Proof.** If there exists strictly feasible points then LCP\((q,A)\) has a solution where \( A \in \tilde{E}_0^s \). Let us consider the subsequences \( \{z^k : k \in \omega\} \). Suppose \( \tilde{z} \) is the limit of the subsequence and \( \tilde{w} = q + A\tilde{z} \). Again we know \( \psi(\tilde{z}, \tilde{w}) < \infty \). So either \( \tilde{z}^T \tilde{w} = 0 \) or \( (\tilde{z}, \tilde{w}) > 0 \). If the first case happen, then \( (\tilde{z}, \tilde{w}) \) is a solution. So let us consider that \( (\tilde{z}, \tilde{w}) > 0 \). Also suppose \( \bar{\tau} \) and \( \bar{A} \) are the limits of the subsequences \( \{r^k : k \in \omega\} \) and \( \{A^k : k \in \omega\} \) respectively. Consider \( \tau^k \) converges to \( \bar{\tau} = \sqrt{r^T \bar{A}^{-1} r} (\beta > 0) \), where \( \bar{A} \) remains positive definite. \( (\tilde{d}_z, \tilde{d}_w) \) be the limits of the sequence of direction \((d_z^k, d_w^k)\). So from the algorithm we get

\[
\tilde{d}_z = -\bar{A}^{-1} \bar{\tau}, \quad \tilde{d}_w = \bar{A} \tilde{d}_z.
\]

Now as \( \{\psi(z^{k+1}, w^{k+1}) - \psi(z^k, w^k)\} \) converges to zero and since \( \lim m_k = \infty \) as \( k \to \infty \), \( \{(z^{k+1}, w^{k+1}) : k \in \omega\} \) and \( \{(z^k + 2^{-(m_k-1)}d_z^k, w^k + 2^{-(m_k-1)}d_w^k) : k \in \omega\} \) converges to \( (\tilde{z}, \tilde{w}) \). As \( m_k \) is the smallest non-negative integers, we have,

\[
\frac{\psi(z^k + 2^{-(m_k-1)}d_z^k, w^k + 2^{-(m_k-1)}d_w^k) - \psi(z^k, w^k)}{2^{-(m_k-1)}} \geq -\sigma \beta^2 \tau_k.
\]

Again on the other hand from the algorithm,

\[
\frac{\psi(z^{k+1}, w^{k+1}) - \psi(z^k, w^k)}{2^{-m_k}} \leq -\sigma \beta^2 \tau_k.
\]

Now taking limit \( k \to \infty \), we write,

\[
\nabla_z \psi(\tilde{z}, \tilde{w})^T \tilde{d}_z + \nabla_w \psi(\tilde{z}, \tilde{w})^T \tilde{d}_w = -\sigma \beta^2 \bar{\tau}.
\]

Again from Lemma 6.1 we know,

\[
(\nabla_z \psi_k)^T d_z^k + (\nabla_w \psi_k)^T d_w^k = -\tau_k \beta^2.
\]

Hence by taking limit \( k \to \infty \), we get

\[
\nabla_z \psi(\tilde{z}, \tilde{w})^T \tilde{d}_z + \nabla_w \psi(\tilde{z}, \tilde{w})^T \tilde{d}_w = -\bar{\tau} \beta^2.
\]

Therefore we arrive at a contradiction. So our proposed algorithm converges to the solution. \( \square \)
7 Numerical illustration

A numerical example is considered to demonstrate the effectiveness and efficiency of the proposed algorithm.

**Example 7.11.** We consider the following example of LCP\((q, A)\), where

\[
A = \begin{pmatrix} 0 & 1 & 1 \\ 2 & 0 & 2 \\ -2 & -5 & 0 \end{pmatrix} \quad \text{and} \quad q = \begin{pmatrix} -4 \\ -7 \\ 10 \end{pmatrix}.
\]

It is easy to show that \(A \in \hat{E}_\alpha^3\). We apply proposed algorithm to find solution of the given problem. According to Theorem 6.50 algorithm converges to solution with \(z^0, w^0 > 0\). To start with we initialize \(\beta = 0.5, \gamma = 0.5, \sigma = 0.2, \epsilon = 0.00001\). We set \(z^0 = \begin{pmatrix} 1 \\ 1 \\ 5 \end{pmatrix}\) and obtain \(w^0 = \begin{pmatrix} 2 \\ 5 \\ 3 \end{pmatrix}\).

Table 1: Summary of computation for the proposed algorithm
Table 1 summarizes the computations for the first 2 iterations, 50th iteration and 96th, 97th iteration and 100th iteration. At the 100th iteration, sequence \( \{z^k\} \) and \( \{w^k\} \) produced by the proposed algorithm converges to the solution of the given LCP \( (q,A) \) i.e. 
\[
z^* = \begin{pmatrix} 1.0714 \\ 1.5714 \\ 2.4285 \end{pmatrix} \quad \text{and} \quad w^* = \begin{pmatrix} 0 \\ 0 \\ 0 \end{pmatrix}.
\]

8 Concluding remark

In this article, we show that LCP\((q,A)\) is processable by Lemke’s algorithm and the solution set of LCP\((q,A)\) is bounded if \( A \in \tilde{E}_0^s \cap P_0 \), a subclass of \( E_0^s \cap P_0 \). It can be shown that non-negative matrices with zero diagonal with at least one \( a_{ij} > 0 \) with \( i \neq j \) is not a \( \tilde{E}_0^s \)-matrix. Whether a matrix class belongs to \( P_0 \cap Q_0 \) or not is difficult to verify. We show that the class identified in this article is a new subclass of \( P_0 \cap Q_0 \) which will motivate further study and applications in matrix theory. Finally we propose an iterative and descent type interior point method to compute solution of LCP\((q,A)\).
