GEOMETRY OF NON-DEGENERATE LOCALLY TAME NON-ISOLATED SINGULARITIES

CHRISTOPHE EYRAL AND MUTSUO OKA

ABSTRACT. We give a criterion to test geometric properties such as Whitney equisingularity and Thom’s $a_f$ condition for new families of (possibly non-isolated) hypersurface singularities that “behave well” with respect to their Newton diagrams. As an important corollary, we obtain that in such families all members have isomorphic Milnor fibrations.

1. Introduction

Let $f(t, z) = f(t, z_1, \ldots, z_n)$ be a non-constant polynomial function on $\mathbb{C} \times \mathbb{C}^n$ such that $f(t, 0) = 0$ for all small $t$. As usual, we write $f_t(z) := f(t, z)$ and we denote by $V(f_t)$ the zero set of $f_t$, which defines a hypersurface in $\mathbb{C}^n$. The goal of this paper is to investigate the local geometry, at singular points, of the hypersurfaces $V(f_t)$ as the parameter $t$ varies. Here, the word “local” always refers to properties associated to (small representatives of) germs at the origin. Our main result is a criterion to test Whitney equisingularity and Thom’s $a_f$ condition for new families of (possibly non-isolated) hypersurface singularities that “behave well” with respect to their Newton diagrams.

To our knowledge, the first result in this direction concerns isolated singularities and was obtained by Briançon in an unpublished lecture notes [1]. It asserts that, for isolated singularities, the family $\{V(f_t)\}_t$ is Whitney equisingular if the Newton boundary of $f_t$ is independent of $t$ and $f_t$ is non-degenerate (in the sense of Kouchnirenko [7]) for all small $t$. Here, the expression “Whitney equisingular” means that there exists a Whitney (b)-regular stratification (in the sense of [5]) of the hypersurface $V(f) := f^{-1}(0)$ (which lies in $\mathbb{C} \times \mathbb{C}^n$) such that the $t$-axis $\mathbb{C} \times \{0\}$ is a stratum. For families of isolated singularities, this simply means that $V(f) \setminus (\mathbb{C} \times \{0\})$ is smooth and Whitney (b)-regular over $\mathbb{C} \times \{0\}$. Note that Whitney equisingularity is quite a strong form of equisingularity. In particular, combined with the Thom–Mather first isotopy theorem [8][16], it implies topological equisingularity, that is, the local, ambient, topological type of $V(f_t)$ at $0$ is independent of $t$ for all small $t$.

2010 Mathematics Subject Classification. 14J70, 14J17, 32S15, 32S25.
Key words and phrases. Non-isolated hypersurface singularity; Whitney equisingularity; Topological equisingularity; Whitney stratification; Thom condition; Milnor fibration; Newton non-degeneracy; Uniform local tameness; Complete intersection variety.

In particular, we do not require the frontier condition to be satisfied. However, note that taking the connected components of a Whitney (b)-regular stratification gives a new such a stratification for which the frontier condition holds (see [5]).
For non-isolated singularities, Whitney equisingularity is more delicate. In particular, for such singularities, the smooth part of \( V(f) \) may be Whitney \((b)\)-regular over the \( t\)-axis without the family \( \{V(f_t)\}_t \) being Whitney equisingular or even without being topologically equisingular. For instance, look at Zariski’s example \( f(t, z_1, z_2) = t^2 z_1^2 - z_2^2 \) for which the smooth part is actually Whitney \((b)\)-regular over \( \mathbb{C} \times \{0\} \), while the local, ambient, topological type of \( V(f_t) \) at \( 0 \), for \( t \neq 0 \), is different from that of \( V(f_0) \) (see [17]).

In [3, Theorem 3.8], we gave a first generalization of Briançon’s theorem for families of non-isolated singularities. Unlike the isolated case, for non-isolated singularities, we should take into account not only the compact faces of the Newton polyhedron (via non-degeneracy) but also the non-compact faces. This led us to the notion of “uniform local tameness” which is a kind of the Newton polyhedron (via non-degeneracy) but also the non-compact isolated singularities, we should take into account not only the compact faces of singularity varieties satisfying the “uniform local tameness” condition. Essentially, the latter condition means the following. First, for a fixed \( t \), if its Newton diagram intersects each coordinate axes (see [17]), and hence Theorem 3.8 of [3] does not apply to this case. It was therefore very desirable to find a new criterion that includes the (much larger) class of functions of the form \( f_t(z) = f_t^1(z) \cdots f_t^{k_0}(z) \). That is the main, but not unique, goal of the present paper.

More precisely, we shall introduce the class of “Newton-admissible” families, which are defined as follows. A family \( \{f_t\}_t \) is Newton-admissible if each \( f_t(z) \) is the product of non-degenerate functions \( f_t^1(z), \ldots, f_t^{k_0}(z) \) with constant Newton boundary (with respect to \( t \)) and such that any subfamily

\[
\{V(f_t^{k_1}, \ldots, f_t^{k_p})\}_t := \left\{ \bigcap_{j=1}^p V(f_t^{k_j}) \right\}_t,
\]

with \( \{k_1, \ldots, k_p\} \subseteq \{1, \ldots, k_0\} \) is a family of non-degenerate complete intersection varieties satisfying the “uniform local tameness” condition. Essentially, the latter condition means the following. First, for a fixed \( t \), the local tameness condition guarantees that for any subset \( I \subseteq \{1, \ldots, n\} \) with

\[
f_t^{k_1}|_{\mathbb{C}^I} \equiv \cdots \equiv f_t^{k_p}|_{\mathbb{C}^I} \equiv 0,
\]

any weight vector \( w = (w_1, \ldots, w_n) \in \mathbb{N} \setminus \{0\} \) whose zero weights \( w_i = 0 \) are located at the places \( i \in I \), and any non-zero small enough complex numbers \( u_i, i \in I \) (say, \( \sum_{i \in I} |u_i|^2 < R_t \) for some \( R_t > 0 \), the \( k_p\)-form

\[
df_t^{k_1}_{t,w} \wedge \cdots \wedge df_t^{k_p}_{t,w}
\]

is nowhere vanishing in the toric variety

\[
V(f_t^{k_1}_{t,w}, \ldots, f_t^{k_p}_{t,w}) \cap \{z \in \mathbb{C}^n \mid (z_i)_{i \in I} = (u_i)_{i \in I}\}.
\]
Here, $f^k_t w$ denotes the face function of $f^k_t$ with respect to the weight vector $w$. A number $R_t$ for which the above property holds is called a radius of local tameness of the set of functions $\{f^k_1, \ldots, f^k_p\}$. Now, when the parameter $t$ varies, we say that the family of varieties $V(f^k_1, \ldots, f^k_p)$ satisfies the “uniform” local tameness condition if there are radii of local tameness $R_t$ that can be chosen to be independent of $t$ for all small $t$ (for a precise definition, see Sections 2 and 3). With this terminology, our main result says that if $\{f_t\}$ is Newton-admissible, then the family of hypersurfaces $\{V(f_t)\}$ is Whitney equisingular; moreover, the corresponding Whitney stratification of $V(f)$ is just the canonical toric stratification (see Theorem 3.3). In the case of a single function (i.e., $k_0 = 1$), the result reduces to Theorem 3.8 of [3].

While the proof of this equisingularity criterion is not easy, its statement is quite simple. Let us emphasize that the assumptions (non-degeneracy and uniform local tameness) are elementary algebraic conditions which can often be checked using a computer. On the other hand, the conclusion (which is geometric in nature) cannot be directly checked by a computer.

Besides Whitney equisingularity, another important geometric property is so-called Thom’s $a_f$ condition. For instance, this condition plays a crucial role in the Thom–Mather second isotopy theorem (see [3, 16]). It also ensures the transversality of the nearby fibres of (germs at 0 of) analytic functions to small spheres, which is a key property to prove the existence of their Milnor fibrations. By a theorem of Parusiński [15] and Briançon–Maisonobe–Merle [2], Whitney’s $(b)$-regularity implies so-called $w_f$ condition (also called Thom’s strict condition), which in turn implies Thom’s $a_f$ condition. Thus, combined with our equisingularity criterion (Theorem 3.3), it follows that if $\{f_t\}$ is a Newton-admissible family, then the canonical toric stratification of $V(f)$ satisfies Thom’s $a_f$ condition (see Theorem 4.1). This theorem can also be proved by a direct explicit calculation using only elementary methods (see Section 7).

Finally, as an important corollary of Theorems 3.3 and 4.1, we shall show that if the family $\{f_t\}$ is Newton-admissible, then for $t$ small enough the Milnor fibrations of $f_t$ and $f_0$ at 0 are isomorphic (see Theorem 5.3). A key observation in the proof of this result is Theorem 5.1 which asserts that Newton-admissible families have so-called “uniform stable radius”. Roughly, a family has a uniform stable radius if there exists a radius $r > 0$ such that the nearby fibres $V(f_t - \eta) := f_t^{-1}(\eta), \eta \neq 0$, are non-singular in the open ball $B_r$, transversely intersect all spheres $S_{\varepsilon_\nu}$ with radius $\varepsilon_\nu \in [\varepsilon', \epsilon] \subseteq (0, r]$, and if this occurs “uniformly” with respect to the deformation parameter $t$ (for a precise definition, see Section 5). In turn, the proof of Theorem 5.1 is based on a “uniform” version of a well-known result according to which any sufficiently small sphere transversely intersects all strata of any given Whitney stratification (see Proposition 5.2).

To complete this introduction, note that working with a product of functions $f^1_t(z), \ldots, f^k_0(z)$ presents an essential new difficulty. Indeed, to prove our main result on Whitney equisingularity, we need to calculate limits of
expressions of the form
\[ df^{k_1}_{I,w}(\rho(s)) \wedge \cdots \wedge df^{k_p}_{I,w}(\rho(s)) \]
along real analytic curves \( \rho(s) \) as \( s \to 0 \), and in general, the limits of the linearly independent 1-forms
\[ df^{k_1}_{I,w}(\rho(s)), \ldots, df^{k_p}_{I,w}(\rho(s)) \]
may be linearly dependent. This phenomenon, which does not happen in the case of a single function, is one of the main difficulties.

2. **Non-degenerate locally tame complete intersection variety**

Let \( z := (z_1, \ldots, z_n) \) be coordinates for \( \mathbb{C}^n \), and let \( f(z) = \sum c_\alpha z^\alpha \) be a non-constant polynomial function which vanishes at the origin. Here, \( \alpha := (\alpha_1, \ldots, \alpha_n) \) is an integer vector, \( c_\alpha \in \mathbb{C} \), and \( z^\alpha \) is a notation for the monomial \( z_1^{\alpha_1} \cdots z_n^{\alpha_n} \). For any \( I \subseteq \{1, \ldots, n\} \), we denote by \( \mathbb{C}^I \) (respectively, \( \mathbb{C}^* \)) the set of points \( (z_1, \ldots, z_n) \in \mathbb{C}^n \) such that \( z_i = 0 \) if \( i \notin I \) (respectively, \( z_i = 0 \) if and only if \( i \notin I \)). In particular, we have \( \mathbb{C}^0 = \mathbb{C}^* = \{0\} \) and \( \mathbb{C}^{*\{1,\ldots,n\}} = \mathbb{C}^n \), where \( \mathbb{C}^* := \mathbb{C} \setminus \{0\} \). Throughout this paper, we are only interested in a local situation, that is, in (arbitrarily small representatives of) germs at the origin.

In this section, we recall the definition of non-degenerate, locally tame, complete intersection varieties already used in [14]. We start with the special case of hypersurfaces.

2.1. **Non-degenerate locally tame hypersurface.** The Newton polyhedron \( \Gamma_+(f) \) of the germ of \( f \) at the origin \( 0 \in \mathbb{C}^n \) (with respect to the coordinates \( z = (z_1, \ldots, z_n) \)) is the convex hull in \( \mathbb{R}^n_+ \) of the set
\[ \bigcup_{c_\alpha \neq 0} (\alpha + \mathbb{R}^n_+) \].

The Newton boundary (also called Newton diagram) of \( f \) is the union of the compact faces of \( \Gamma_+(f) \). It is denoted by \( \Gamma(f) \).

For any non-zero weight vector \( w := (w_1, \ldots, w_n) \in \mathbb{N}^n \setminus \{0\} \), let us denote by \( \ell_w \) the restriction to \( \Gamma_+(f) \) of the linear map
\[ x := (x_1, \ldots, x_n) \in \mathbb{R}^n \mapsto \sum_{i=1}^{n} w_ix_i \in \mathbb{R} \].

Let \( d(w; f) \) be the minimal value of \( \ell_w \), and let \( \Delta(w; f) \) be the face of \( \Gamma_+(f) \) defined by
\[ \Delta(w; f) = \{ x \in \Gamma_+(f) \mid \ell_w(x) = d(w; f) \} \].

Note that if the \( w_i \)’s are positive for all \( i \), then \( \Delta(w; f) \) is a (compact) face of \( \Gamma(f) \). Finally, put \( I(w) := \{ i \in \{1, \ldots, n\} \mid w_i = 0 \} \). By definition, the non-compact Newton boundary is the union of the usual Newton boundary \( \Gamma(f) \) together with the “essential” non-compact faces of \( \Gamma_+(f) \), that is, the non-compact faces \( \Delta(w; f) \) such that the restriction of \( f \) to \( \mathbb{C}^I(w) \) identically vanishes.
The germ at 0 of the hypersurface $V(f) := f^{-1}(0)$ is called \textit{(Newton) non-degenerate} if for any positive weight vector $w$, the toric hypersurface

$$V^*(f_w) := \{ z \in \mathbb{C}^n | f_w(z) = 0 \}$$

is a reduced non-singular hypersurface in the complex torus $\mathbb{C}^n$. This means that $f_w$ has no critical point in $V^*(f_w)$—equivalently, by Euler identity, in $\mathbb{C}^n$—that is, the 1-form $df_w$ is nowhere vanishing in $V^*(f_w)$. Here, we write $f_w$ for the face function

$$z \mapsto \sum_{a \in \Delta(w, f)} c_a z^a$$

of $f$ with respect to $w$. We emphasize that $V^*(f_w)$ is globally defined in $\mathbb{C}^n$.

Let $\mathcal{V}_f$ be the set of all subsets $I \subseteq \{1, \ldots, n\}$ such that the restriction of $f$ to $\mathbb{C}^I$ identically vanishes. We say that $\mathbb{C}^I$ is a vanishing (respectively, a non-vanishing) coordinate subspace for $f$ if $I \in \mathcal{V}_f$ (respectively, if $I \notin \mathcal{V}_f$). For any $u_1, \ldots, u_m \in \mathbb{C}^n$ $(m \leq n)$, let $\mathbb{C}^n(u_1, \ldots, u_m)$ denote the set of points $(z_1, \ldots, z_n) \in \mathbb{C}^n$ such that $z_i = u_i$ for $1 \leq j \leq m$. We say that the germ of $V(f)$ at 0 is \textit{locally tame} if there is a positive number $R(f)$ such that for any non-empty subset $I := \{i_1, \ldots, i_m\} \in \mathcal{V}_f$, any non-zero weight vector $w$ with $I(w) = I$, and any non-zero complex numbers $u_1, \ldots, u_m$ satisfying the inequality

$$\sum_{j=1}^m |u_j|^2 < R(f),$$

the toric hypersurface

$$V^*(f_w) \cap \mathbb{C}^n(u_1, \ldots, u_m)$$

is a reduced non-singular hypersurface in $\mathbb{C}^n(u_1, \ldots, u_m)$. This means that $f_w$ has no critical point in $V^*(f_w) \cap \mathbb{C}^n(u_1, \ldots, u_m)$—equivalently, in $\mathbb{C}^n(u_1, \ldots, u_m)$—as a function of the $n - m$ variables $z_{m+1}, \ldots, z_n$, where $\{i_{m+1}, \ldots, i_n\} = \{1, \ldots, n\} \setminus \{i_1, \ldots, i_m\}$. In other words, $f_w$ is a non-degenerate function of the variables $(z_i)_{i \notin I}$, with the other variables $(z_i)_{i \in I}$ being fixed in the ball $\sum_{i \in I} |z_i|^2 < R(f)$. Any positive number $R(f)$ for which the above property holds is called a \textit{radius of local tameness} of $f$.

\subsection{Non-degenerate locally tame complete intersection variety.}

Let us now consider $k_0$ non-constant polynomial functions $f^1(z), \ldots, f^{k_0}(z)$ which all vanish at the origin. We say that the germ at 0 of the variety

$$V(f^1, \ldots, f^{k_0}) := \{ z \in \mathbb{C}^n | f^1(z) = \cdots = f^{k_0}(z) = 0 \}$$

is a germ of a \textit{non-degenerate} complete intersection variety if for any positive weight vector $w$, the toric variety

$$V^*(f^1_w, \ldots, f^{k_0}_w) := \{ z \in \mathbb{C}^n | f^1_w(z) = \cdots = f^{k_0}_w(z) = 0 \}$$

is a reduced, non-singular, complete intersection variety in $\mathbb{C}^n$. This means that the $k_0$-form

$$df^1_w \wedge \cdots \wedge df^{k_0}_w$$

is nowhere vanishing in $V^*(f^1_w, \ldots, f^{k_0}_w)$. Again, let us emphasize that the variety $V^*(f^1_w, \ldots, f^{k_0}_w)$ is globally defined in $\mathbb{C}^n$.

Finally, we say that the germ at 0 of $V(f^1, \ldots, f^{k_0})$ is a germ of a \textit{locally tame} complete intersection variety if there is a positive number

of functions \( \{ f^1, \ldots, f^{k_0} \} \) such that for any non-empty subset \( I := \{ i_1, \ldots, i_m \} \in V_{f^1} \cap \cdots \cap V_{f^{k_0}} \), any non-zero weight vector \( w \) with \( I(w) = I \), and any non-zero complex numbers \( u_{i_1}, \ldots, u_{i_m} \) satisfying the inequality

\[
\sum_{j=1}^{m} |u_{i_j}|^2 < R(f^1, \ldots, f^{k_0}),
\]

the toric variety

\[
V^*(f^1_w, \ldots, f^{k_0}_w) \cap \mathbb{C}^{s_n}(u_{i_1}, \ldots, u_{i_m})
\]

is a reduced, non-singular, complete intersection variety in \( \mathbb{C}^{s_n}(u_{i_1}, \ldots, u_{i_m}) \). Again, this means that the \( k_0 \)-form \( df^1_w \wedge \cdots \wedge df^{k_0}_w \) is nowhere vanishing in \( V^*(f^1_w, \ldots, f^{k_0}_w) \cap \mathbb{C}^{s_n}(u_{i_1}, \ldots, u_{i_m}) \). Any positive number \( R(f^1, \ldots, f^{k_0}) \) satisfying the above property is called a radius of local tameness of the set of functions \( \{ f^1, \ldots, f^{k_0} \} \).

3. Whitney equisingularity

Now, let \((t, z) := (t, z_1, \ldots, z_n)\) be coordinates for \( \mathbb{C} \times \mathbb{C}^n \), and for any \( k \in K_0 := \{1, \ldots, k_0\} \), let \( f^k : \mathbb{C} \times \mathbb{C}^n \to \mathbb{C} \) be a non-constant polynomial function such that \( f^k(t, 0) = 0 \) for all \( t \). Put

\[
f(t, z) := f^1(t, z) \cdots f^{k_0}(t, z),
\]

and as usual, write \( f_k(z) := f(t, z) \) and \( f^k(t, z) := f^k(t, z) \). We suppose that for any sufficiently small \( t \), the following two conditions hold true:

- for any \( k \in K_0 \), the Newton boundary \( \Gamma(f^k) \) is independent of \( t \) (especially, \( V_{f^k} \) is independent of \( t \));
- for any \( \{ k_1, \ldots, k_p \} \subseteq K_0 \), the germ at \( 0 \) of \( V(f^{k_1}_1, \ldots, f^{k_p}_p) \) is a germ of a non-degenerate complete intersection variety.

Then, by [11, Chap. V, Lemma (2.8.2)], there is a neighbourhood of the origin in which any subset of the form

\[
(3.1) \quad \bigcap_{k \in K} V(f^k) \cap (\mathbb{C} \times \mathbb{C}^*)
\]

is non-singular, where \( K \subseteq K_0 \) and \( I \subseteq \{1, \ldots, n\} \). Note that if for all \( k \in K \) the restriction \( f^k|_{\mathbb{C} \times \mathbb{C}^I} \) is not identically zero, then the subset \( (3.1) \) is also a complete intersection variety (ibid.). Hereafter, we shall write

\[
V^{*I}(f^k) := V(f^k) \cap (\mathbb{C} \times \mathbb{C}^{*I})
\]

It follows that the collection \( S \) of all non-empty subsets of the form

\[
S^I(K) := \{ (t, z) \in \mathbb{C} \times \mathbb{C}^{*I} \mid f^k(t, z) = 0 \Leftrightarrow k \in K \}
\]

is a complex analytic stratification of \( V(f) \). We call \( S \) the canonical toric stratification of \( V(f) \). Note that it includes \( S^0(K_0) = \mathbb{C} \times \{0\} \) (i.e., the \( t \)-axis) as a stratum.

Remark 3.1. For a given \( I \), if \( S^I(K) \neq \emptyset \), then \( K \) necessarily contains all \( k \)'s for which \( f^k|_{\mathbb{C} \times \mathbb{C}^I} \equiv 0 \) plus possibly some other \( k \)'s such that \( f^k|_{\mathbb{C} \times \mathbb{C}^I} \neq 0 \).
To state the results of this paper, we need to strengthen a bit the assumptions made above. Precisely we fix the following terminology.

**Definition 3.2.** We say that the family \( \{f_t\}_{t} \) is *Newton-admissible* if for any sufficiently small \( t \), the following two conditions hold true:

- for any \( k \in K_0 \), the Newton boundary \( \Gamma(f_t^k) \) is independent of \( t \);
- for any \( \{k_1, \ldots, k_p\} \subseteq K_0 \), the germ at \( 0 \) of \( V(f_t^{k_1}, \ldots, f_t^{k_p}) \) is a germ of a non-degenerate, locally tame, complete intersection variety, and there is a radius of local tameness \( R(f_t^{k_1}, \ldots, f_t^{k_p}) \) for the corresponding set of functions \( \{f_t^{k_1}, \ldots, f_t^{k_p}\} \) which is greater than some positive number \( R \) independent of \( t \) and of the choice of the subset \( \{k_1, \ldots, k_p\} \).

The inequality \( R(f_t^{k_1}, \ldots, f_t^{k_p}) > R \), which holds for all small \( t \), expresses the fact that the family \( \{V(f_t^{k_1}, \ldots, f_t^{k_p})\}_{t} \) is uniformly locally tame.

The main result of this section is stated as follows.

**Theorem 3.3.** If the family \( \{f_t\}_{t} \) is Newton-admissible, then the canonical toric stratification \( S \) of \( V(f) \) is Whitney (b)-regular. In particular, the corresponding family of hypersurfaces \( \{V(f_t)\}_{t} \) is Whitney equisingular.

Combined with the Thom–Mather first isotopy theorem (see [8],[16]), Theorem 3.3 shows that if \( \{f_t\}_{t} \) is a Newton-admissible family, then the local, ambient, topological type of \( V(f_t) \) at \( 0 \) is independent of \( t \) for all small \( t \).

Theorem 3.3 is proved in Section 6. It extends our previous result [3, Theorem 3.8] to a much larger class of hypersurfaces with non-isolated singularities.

The Whitney (b)-regularity along the \( t \)-axis for strata of the form \( S^J(L) \), \( J \notin V(f)_t \), \( k \in L \), is already obtained in [11, Chap. V, Theorem (2.8)]. However, this is not enough to ensure that the family \( \{V(f_t)\}_{t} \) is Whitney equisingular (or even topologically equisingular). We also need that pairs of strata \( S^I(L) \subseteq S^J(L) \), with \( I \in V(f)_t \) for \( k \in K \) and \( J \notin V(f)_t \) for \( k \in L \), satisfy the Whitney (b)-regularity condition. On the other hand, if we only ask for Whitney’s (b)-regularity only along the \( t \)-axis for strata of the form \( S^J(L) \), \( J \notin V(f)_t \), \( k \in L \), then the uniform local tameness assumption is not needed; only the stability of the Newton boundary and the non-degeneracy condition are required.

The topological equisingularity can be also obtained (it is done in [11, Chap. V, Corollary (2.11)]) under the stability of the Newton boundary, the non-degeneracy condition, and an additional assumption which guarantees the independence in \( t \) of the face functions \( f_{t,w}, f_{k_0}^{k_0} \) of \( f_1, \ldots, f_{k_0}^{k_0} \) with respect to so-called “essential” weight vectors \( w \) (here, “essential” means \( \emptyset \neq I(w) \in V(f) \cap \cdots \cap V(f_k) \) and \( V(f_1, \ldots, f_{k_0}^{k_0}) \neq \emptyset \)).

In [10, §8], another Whitney stratification of the pair \( (V(f), \mathbb{C} \times \{0\}) \)—with a larger number of strata than ours—is constructed under a different, rather technical, assumption (so-called “simultaneous IND-condition”). Under this condition, both Whitney and topological equisingularities do hold too.

The following is an immediate corollary of Theorem 3.3.
Corollary 3.4. If the family \( \{ f_t \} \) is Newton-admissible, then for any sufficiently small \( t \), the partition \( S_t = \{ S_t^I(K) \} \) of \( \{ t \} \times \mathbb{C}^n \), defined by

\[
S_t^I(K) := S_t^I(K) \cap (\{ t \} \times \mathbb{C}^n)
\]

where \( I \subseteq \{ 1, \ldots, n \} \) and \( K \subseteq K_0 \), is a Whitney \((b)\)-regular stratification of \( V(f_t) \) in a neighbourhood of the origin of \( \mathbb{C}^n \) which is independent of \( t \). (Here, we identify \( \{ t \} \times \mathbb{C}^n \) with \( \mathbb{C}^n \).) More precisely, there exist an open disc \( D_r \subseteq \mathbb{C} \) with radius \( \tau > 0 \) and an open ball \( B_r \subseteq \mathbb{C}^n \) with radius \( r > 0 \) centred at the origins of \( \mathbb{C} \) and \( \mathbb{C}^n \), respectively, such that for any \( t \in D_r \), the collection \( \{ S_t^I(K) \} \) is a Whitney \((b)\)-regular stratification of \( V(f_t) \) in \( B_r \).

Indeed, if \( \{ f_t \} \) is Newton-admissible, then there exist \( \tau, r > 0 \) such that for any \( t \in D_r \), the space \( \{ t \} \times \mathbb{C}^n \) transversely intersects all the strata of \( S \) in the neighbourhood \( D_r \times B_r \) of the origin of \( \mathbb{C} \times \mathbb{C}^n \), and it is well known that Whitney \((b)\)-regular stratifications are preserved under transverse intersections (see [5]).

Remark 3.5. If the family \( \{ f_t \} \) is Newton-admissible, then Theorem 3.3 shows that the collection of subsets \( \{ S_t^I(K_0) \} \subseteq \{ 1, \ldots, n \} \) is a Whitney \((b)\)-regular stratification of \( V(f_1^1, \ldots, f_t^{k_0}) \) with the \( t \)-axis as a stratum. In particular, by the Thom–Mather first isotopy theorem again, the local, ambient, topological type at \( 0 \) of the complete intersection variety \( V(f_1^1, \ldots, f_t^{k_0}) \) is independent of \( t \) for all small \( t \).

Similarly, Corollary 3.4 shows that if \( \{ f_t \} \) is Newton-admissible, then for any sufficiently small \( t \), the collection of subsets \( \{ S_t^I(K_0) \cap (\{ t \} \times \mathbb{C}^n) \} \subseteq \{ 1, \ldots, n \} \) is a Whitney \((b)\)-regular stratification of the complete intersection variety \( V(f_1^1, \ldots, f_t^{k_0}) \) in a neighbourhood of the origin of \( \mathbb{C}^n \) which is independent of \( t \).

Theorem 3.3 has several other important corollaries. They are stated in the following two sections.

4. Thom’s \( a_f \) condition

Pick a sufficiently small representative of \((\text{the germ at } 0 \text{ of } f)\) so that 0 is the only possible critical value of \( f \). Then the critical locus \( \Sigma f \) of \( f \) is contained in \( V(f) \). We say that a Whitney \((a)\)-regular stratification of \( V(f) \) satisfies Thom’s \( a_f \) condition if for any stratum \( S \), any point \( (\tau, q) \in S \), and any sequence \( \{(\tau_m, q_m)\}_m \not\in V(f) \) such that

\[
(\tau_m, q_m) \to (\tau, q) \quad \text{and} \quad T_{(\tau_m, q_m)} V(f - f(\tau_m, q_m)) \to T
\]

as \( m \to \infty \), we have \( T_{(\tau, q)} S \subseteq T \), where

\[
V(f - f(\tau_m, q_m)) := \{ (t, z) \in \mathbb{C} \times \mathbb{C}^n \mid f(t, z) = f(\tau_m, q_m) \}
\]

and \( T_{(\tau_m, q_m)} V(f - f(\tau_m, q_m)) \) is the tangent space of \( V(f - f(\tau_m, q_m)) \) at \( (\tau_m, q_m) \). Similarly, \( T_{(\tau, q)} S \) is the tangent space of \( S \) at \( (\tau, q) \).

Combined with a result of Parusinski [13] and Briançon–Maisonobe–Merle [2], Theorem 3.3 above implies the following statement.

Theorem 4.1. If the family \( \{ f_t \} \) is Newton-admissible, then the canonical toric stratification \( S \) of \( V(f) \) satisfies Thom’s \( a_f \) condition.
Indeed, by Theorem 5.3, the stratification $S$ is Whitney (b)-regular. Then Theorem p. 99 of [15] or Theorem 4.3.2 of [2] tell us that $S$ satisfies so-called $w_f$ condition, and hence, Thom’s $a_f$ condition. Theorem 4.1 can also be proved by a direct explicit calculation, without invoking [15] or [2] (see Section 6). We thank Lê Dũng Tráng who pointed out us the result of Parusiński, Briançon, Maisonobe and Merle, which considerably simplifies our original direct proof.

By a straightforward extension of [14] Theorem 5], if for any subset $\{k_1, \ldots, k_p\} \subseteq K_0$, the germ at $(0, 0) \in \mathbb{C} \times \mathbb{C}^n$ of the variety $V(f_{k_1}, \ldots, f_{k_p})$ is a germ of a non-degenerate, locally tame, complete intersection variety, then the canonical toric stratification of $V(f)$ satisfies Thom’s $a_f$ condition too. However, note that in this latter statement, the assumptions refer to the functions $f_{k_i}(t, z)$ whereas in Theorem 4.1 they refer to the members $f_{t}^{k_i}(z)$ of the families $\{f_{t}^{k_i}\}_{t}$ defined by the functions $f_{t}^{k_i}(t, z)$.

The following proposition, which asserts the “uniform” smoothness of the nearby fibres of a Newton-admissible family, will be very useful.

**Proposition 4.2.** If the family $\{f_{t}\}_{t}$ is Newton-admissible, then the nearby fibres $V(f_{t} - \eta)$, $\eta \neq 0$, of the functions $f_{t}$ are “uniformly” non-singular with respect to the deformation parameter $t$. That is, there exist positive numbers $\delta, \tau, r$ such that for any $0 < |\eta| \leq \delta$ and any $0 \leq |t| \leq \tau$, the level hypersurface $V(f_{t} - \eta)$ is non-singular in $B_{r}$. (Here, $B_{r}$ denotes the open ball with radius $r$ centred at the origin.)

The proof of Proposition 1.2 is given in Section 8. In particular, this proposition implies that, in $B_{r}$, the critical locus $\Sigma f_{t}$ of $f_{t}$ is contained in $V(f_{t})$ for any $|t| \leq \tau$, and hence for any $z \in B_{r} \setminus \Sigma f_{t}$ the tangent space $T_{z}V(f_{t} - f_{t}(z))$ exists. We can thus state the following corollary of Theorem 4.2.

**Corollary 4.3.** If the family $\{f_{t}\}_{t}$ is Newton-admissible, then the stratifications $S_{t}$ of $V(f_{t})$ defined in Corollary 3.2 satisfy Thom’s $a_{f}$ condition “uniformly” with respect to the parameter $t$, provided that the latter is small enough. More precisely, there exist an open disc $D_{r} \subseteq \mathbb{C}$ with radius $\tau > 0$ and an open ball $B_{r} \subseteq \mathbb{C}^{n}$ with radius $r > 0$ centred at the origins of $\mathbb{C}$ and $\mathbb{C}^{n}$, respectively, such that for any $t \in D_{r}$, any stratum $S \in S_{t}$, any point $q \in S$, and any sequence $\{q_{m}\}_{m} \in B_{r} \setminus V(f_{t})$ such that

$$q_{m} \to q$$

and $T_{q_{m}}V(f_{t} - f_{t}(q_{m})) \to T$ as $m \to \infty$, we have $T_{q}S \subseteq T$.

5. Milnor fibrations

The main result of this section is Theorem 5.3. It asserts that if the family $\{f_{t}\}_{t}$ is Newton-admissible, then the Milnor fibrations of $f_{t}$ and $f_{0}$ at $0$ are isomorphic. A key ingredient of the proof is Theorem 5.1 which says that Newton-admissible families have a “uniform stable radius.”

Before stating the results, let us then recall the definition of “uniform stable radius.” By a result of Hamm and Lê Dũng Tráng [6] Lemme (2.1.4), we know that for each $t$ there exists a positive number $r_{t} > 0$ such that for any pair $(\varepsilon_{t}, \varepsilon'_{t})$ with $0 < \varepsilon'_{t} \leq \varepsilon_{t} \leq r_{t}$, there exists $\delta(\varepsilon_{t}, \varepsilon'_{t}) > 0$ such that for
any non-zero complex number \( \eta \) with \( 0 < |\eta| \leq \delta(\varepsilon_t, \varepsilon_t') \), the hypersurface \( V(f_t - \eta) \) is non-singular in \( B_r \), and transversely intersects the sphere \( S_{\varepsilon''} \) for any \( \varepsilon'' \leq \varepsilon_t \). Any such a number \( r \) is called a stable radius for the Milnor fibration of \( f_t \) at \( 0 \). Here, \( B_r \subseteq \mathbb{C}^n \) is the open ball with radius \( r \) centred at \( 0 \) and \( S_r \) denotes the boundary of the corresponding closed ball \( B_r \). Now, following [10, §3], we say that the family \( \{f_t\}_t \) has a uniform stable radius if there exist \( \tau > 0 \) and \( r > 0 \) such that for any pair \( (\varepsilon, \varepsilon') \) with \( 0 < \varepsilon' \leq \varepsilon \leq r \), there exists \( \delta(\varepsilon, \varepsilon') > 0 \) such that for any non-zero complex number \( \eta \) with \( 0 < |\eta| \leq \delta(\varepsilon, \varepsilon') \), the hypersurface \( V(f_t - \eta) \) is non-singular in \( B_r \) and transversely intersects the sphere \( S_{\varepsilon''} \) for any \( \varepsilon'' \leq \varepsilon' \leq \varepsilon \) and for any \( t \) in the closed disc \( D_\tau := \{t \in \mathbb{C} \mid 0 \leq |t| \leq \tau \} \). Any such a number \( r \) is called a uniform stable radius for \( \{f_t\}_t \).

**Theorem 5.1.** If the family \( \{f_t\}_t \) is Newton-admissible, then it has a uniform stable radius.

Theorem 5.1 is proved in Section 10. The proof is based on the following proposition (proved in Section 9) which is interesting itself. It is well known that for a given \( t \), small spheres are transverse to the strata of \( S_t \). The proposition says that, under the Newton-admissibility condition, this property holds “uniformly” in \( t \). The precise statement is as follows.

**Proposition 5.2.** If the family \( \{f_t\}_t \) is Newton-admissible, then there exists a neighbourhood \( D_\tau \times B_r \) of the origin of \( \mathbb{C} \times \mathbb{C}^n \) such that for any \( 0 < r' \leq r \) and any \( t \in D_\tau \), the sphere \( \{t\} \times S_{r'} \) transversely intersects \((\{t\} \times \mathbb{C}^n) \cap S \) for any stratum \( S \in S \), where \( S \) is the stratification constructed in Theorem 3.3 and \( S_{r'} \) is the sphere with radius \( r' \) centred at the origin of \( \mathbb{C}^n \).

Combined with [9, Lemma 2], Theorem 5.1 implies the main result of this section the statement of which is as follows.

**Theorem 5.3.** If the family \( \{f_t\}_t \) is Newton-admissible, then the Milnor fibrations of \( f_t \) and \( f_0 \) at \( 0 \) are isomorphic for all small \( t \).

The rest of the paper is devoted to the proofs of Theorems 3.3 and 5.1 (we also give a direct proof of Theorem 5.1) and to the proofs of Propositions 4.2 and 5.2.

6. **Proof of Theorem 3.3**

It is inspired from the proofs of [10, Theorem (5.1)], [11, Chap. V, Theorem (2.8)], [3, Theorem 3.8] and [4, Theorem 3.14].

We shall use the following terminology. A non-singular holomorphic \( k \)-form \( \omega \) is called decomposable at \((t, z)\) if there exist linearly independent holomorphic 1-forms \( \omega_1, \ldots, \omega_k \) in a neighbourhood of \((t, z)\) such that

\[
\omega(t, z) = \omega_1(t, z) \land \cdots \land \omega_k(t, z).
\]

To such a form, we can associate an \((n+1-k)\)-dimensional subspace \( \omega(t, z)^\perp \) of the tangent space \( T_{(t,z)}(\mathbb{C} \times \mathbb{C}^n) \) defined by

\[
\omega(t, z)^\perp := \{v \in T_{(t,z)}(\mathbb{C} \times \mathbb{C}^n) \mid \iota_v(\omega(t, z)) = 0\},
\]

where \( \iota_v(\omega(t, z)) \) is the inner derivative of \( \omega(t, z) \) by \( v \).
6.1. Plan of the proof. To prove that our stratification $S$ is Whitney (b)-regular, it suffices to show that for any $I \subseteq J \subseteq \{1, \ldots, n\}$ and any $L \subseteq K \subseteq K_0$ with $S^I(K) \cap \overline{S^J(L)} \neq \emptyset$, the “big” stratum $S^J(L)$ is Whitney (b)-regular over the “small” stratum $S^I(K)$ at any point

$$(\tau, q) = (\tau, q_1, \ldots, q_n) \in S^I(K) \cap \overline{S^J(L)}$$

sufficiently close to the origin. Here, $\overline{S^J(L)}$ denotes the closure of $S^J(L)$.

To simplify, we shall assume:

$$\emptyset \neq I = \{1, \ldots, n_I\} \subseteq J = \{1, \ldots, n\} \quad \text{and} \quad L = \{1, \ldots, k_L\} \subseteq K.$$

(For the case $I = \emptyset$, see [6.7].) In particular, since $(\tau, q) \in S^I(K)$, we have $q_i \neq 0$ if and only if $1 \leq i \leq n_I$.

Pick real analytic paths $\rho(s) := (t(s), z(s))$ and $\rho'(s) := (t'(s), z'(s))$ such that:

1. $\rho(0) = \rho'(0) = (\tau, q)$;
2. $\rho'(s) \in S^I(K)$ and $\rho(s) \in S^J(L)$ for $s \neq 0$.

Write $z(s) = (z_1(s), \ldots, z_n(s))$ and $z'(s) = (z'_1(s), \ldots, z'_n(s))$, and look at the Taylor expansions:

$$t(s) = t_0 s^{w_0} + b_0 s^{w_0+1} + \cdots, \quad z_1(s) = a_1 s^{w_i} + b_1 s^{w_i+1} + \cdots,$$

$$t'(s) = t'_0 s^{w'_0} + b'_0 s^{w'_0+1} + \cdots, \quad z'_1(s) = a'_1 s^{w'_i} + b'_1 s^{w'_i+1} + \cdots,$$

where $w_i = 0$ and $a_i = q_i$ for $1 \leq i \leq n_I$ while $w_i > 0$ and $a_i \neq 0$ for $i > n_I$.

The coefficients $t_0$ and $t'_0$ are also assumed to be non-zero. Note that if $\tau \neq 0$, then $w_0 = w'_0 = 0$ and $t_0 = t'(0) = \tau = t'(0) = t'_0$; if $\tau = 0$, then $w_0, w'_0 > 0$ and $t(0) = t'(0) = 0$. Throughout, the dots “$\cdots$” stand for the terms of higher degree in $s$. Note that if $i > n_I$, then $z'_i(s) = 0$ for any $s$.

Hereafter, we shall write $w := (w_1, \ldots, w_n)$ and $a := (a_1, \ldots, a_n)$. Put

$$\ell(s) := (\ell_0(s), \ell_1(s), \ldots, \ell_n(s)),$$

where

$$\begin{cases}
\ell_0(s) := t(s) - t'(s) \\
\ell_i(s) := z_i(s) - z'_i(s) = \begin{cases}
(b_i - b'_i)s + \cdots & \text{for } 1 \leq i \leq n_I, \\
a_i s^{w_i} + \cdots & \text{for } n_I + 1 \leq i \leq n.
\end{cases}
\end{cases}$$

By reordering, we may suppose $w_{n_I + 1} \leq w_{n_I + 2} \leq \cdots \leq w_n$. We shall write

$$w_{\min} := w_{n_I + 1} = \cdots = w_{n_I + m_I}$$

($m_I \geq 1$) for the minimal value of these weights.

Let $\ell_I := \min \{ \ell_i(s) \mid 0 \leq i \leq n \}$, where $\ell_i(s)$ is the order in $s$ of the $i$th component $\ell_i(s)$ of $\ell(s)$, and let

$$\ell := \lim_{s \to 0} \frac{\ell(s)}{\|\ell(s)\|} = \lim_{s \to 0} \frac{\ell(s)}{|s|^{\ell_I}} \quad \text{and} \quad T_{\infty} := \lim_{s \to 0} T_{\rho(s)} S^J(L).$$

Here, $T_{\rho(s)} S^J(L)$ denotes the (complex) tangent space of $S^J(L)$ at $\rho(s)$, which is given by

$$T_{\rho(s)} S^J(L) = (df^1(\rho(s)) \wedge \cdots \wedge df^{k_L}(\rho(s)))^\perp.$$

where \T_{(\tau, q)}^*(\mathbb{C} \times \mathbb{C}^n) denotes the cotangent space. Clearly,
T_\infty = \omega_\infty^\perp,
and to prove (6.1), we must show that \ell_\infty \in \omega_\infty^\perp. For that purpose, we shall prove that \omega_\infty is decomposable, that is, there exist linearly independent 1-forms \omega_1, \ldots, \omega_{k_L} such that \omega_\infty = \omega_1 \wedge \cdots \wedge \omega_{k_L}. Therefore, to prove that \ell_\infty \in \omega_\infty^\perp, it will be enough to show that \omega_k(\ell_\infty) = 0 for all 1 \leq k \leq k_L. Here, the main difficulty is that, in general, if \mathbb{C}^I is a vanishing coordinate subspace for some of the functions f^k, then the limits of the 1-forms df^1(\rho(s)), \ldots, df^{k_L}(\rho(s)) as s \to 0 are not linearly independent. We shall solve this problem using the same subterfuge as in [4, 10, 12, 14] and substituting to the corresponding differential df^k(\rho(s)) a term of the form
\[ df^k(\rho(s)) + \sum_{i=1}^{k-1} c_{k,i}(s) df^i(\rho(s)), \]
where \( c_{k,i}(s) \) are suitable polynomials.

The plan of the proof is as follows. First, in \S 6.2, using the uniform local tameness condition and the subterfuge mentioned above, we construct the forms \omega_\infty corresponding to the functions f^k having \mathbb{C}^I as a vanishing coordinate subspace (i.e., I \in \mathcal{V}_J^k). Then, using the non-degeneracy condition, we construct the forms \omega_k corresponding to the functions f^k such that I \notin \mathcal{V}_J^k (see \S 6.3). In \S 6.4 we combine the results of \S 6.2 and 6.3 to deduce that \omega_\infty = \omega_1 \wedge \cdots \wedge \omega_{k_L}. Finally, in \S 6.5 (respectively, in \S 6.6), we show that \omega_k(\ell_\infty) = 0 for the indices k such that I \in \mathcal{V}_J^k (respectively, I \notin \mathcal{V}_J^k).
6.2. Construction of the forms \( \omega_k \) corresponding to the functions \( f^k \) such that \( I \in \mathcal{V}_{f^k} \). Let \( L' \subseteq L = \{1, \ldots, k_L\} \) be the subset of all indices \( k \) for which \( \mathbb{C}^l \) is a vanishing coordinate subspace for \( f^k_{1} \), that is,

\[
L' := \{ k \in L \mid I \in \mathcal{V}_{f^k} \}.
\]

(We remind that \( \mathcal{V}_{f^k} \) is independent of \( t \).) To simplify, we shall assume that \( L' = \{1, \ldots, k_{L'}\} \). By multiplying suitable monomials in the variables \((z_i)_{i \in J \setminus I}\) to the functions \( f^k_{I}(z) \) if necessary, we may also assume that

\[
d(w; f^1_{I}) = \cdots = d(w; f^k_{I'}),
\]
as such an operation does not change anything to the stratum \( S^I(L) \). Let us denote by \( d \) this common value which, by the constancy of the Newton boundary, does not depend on \( t \). Then we have the following lemma. Its statement is similar to \cite[Lemma (5.11)]{10} and \cite[Chap. V, Lemma (2.8.19)]{11}. However its assumptions, which are those of Theorem \ref{thm3.3} are different (see the comments that follow the statement of Theorem \ref{thm3.3}).

**Lemma 6.1.** After renumbering the functions \( f^1, \ldots, f^{k_{L'}} \) if necessary, we can find polynomials \( c_{k,l}(s) \) for \( 1 \leq l < k \leq k_{L'} \) such that if we write

\[
df^k (\rho(s)) + \sum_{l=1}^{k-1} c_{k,l}(s) df^l (\rho(s)) = \omega_k s^{v_k} + \cdots,
\]

with \( \omega_k \neq 0 \) for \( 1 \leq k \leq k_{L'} \), then \( \omega_1, \ldots, \omega_{k_{L'}} \) are linearly independent cotangent vectors in \( T^*(\chi,\zeta) (\mathbb{C} \times \mathbb{C}^n) \) and \( \nu_1 \leq \cdots \leq \nu_{k_{L'}} \leq d - w_{\min} \).

**Proof.** It is on the same pattern as the proofs of \cite[Lemma (5.11)]{10} and \cite[Chap. V, Lemma (2.8.19)]{11}. We divide it into two steps.

**First step.** Take any \( 1 \leq k \leq k_{L'} \), and write \( f^k_{\chi,w} \) (respectively, \( f^k_{\chi,w} \)) for the face function of \( f^k_{\chi} \) (respectively, of \( f^k \)) with respect to the weight vector \( w = (w_1, \ldots, w_n) \) (respectively, the weight vector \( \tilde{w} := (w_0, w) \)). Since \( \Gamma(f^k_{\chi}) \) is independent of \( t \), we have

\[
\begin{align*}
\frac{\partial f^k_{\chi}}{\partial \tau} (\rho(s)) &= \frac{\partial f^k_{\chi}}{\partial t} (t_0, a) s^d + \cdots, \\
\frac{\partial f^k_{\chi}}{\partial z_i} (\rho(s)) &= \frac{\partial f^k_{\chi,w}}{\partial z_i} (a) s^{d - w_i} + \cdots,
\end{align*}
\]

so that if \( L'' \subseteq L' \setminus \{k\} \) and \( c_l(s), l \in L'' \), are arbitrary polynomials, then

\[
\varphi^k (s) := df^k (\rho(s)) + \sum_{l \in L''} c_l(s) df^l (\rho(s))
\]

\[
= \left( \left( \frac{\partial f^k_{\chi,w}}{\partial t} (t_0, a) + \sum_{l \in L''} c_l(0) \frac{\partial f^l_{\chi,w}}{\partial t} (t_0, a) \right) s^d + \cdots \right) dt + \\
\sum_{i=1}^n \left( \left( \frac{\partial f^k_{\chi,w}}{\partial z_i} (a) + \sum_{l \in L''} c_l(0) \frac{\partial f^l_{\chi,w}}{\partial z_i} (a) \right) s^{d - w_i} + \cdots \right) dz_i.
\]
Claim 6.2. In the above expression, at least one of the coefficients
\[
\frac{\partial f^j_{\tau,w}}{\partial z_i}(a) + \sum_{l \in L'} c_l(0) \frac{\partial f^l_{\tau,w}}{\partial z_i}(a),
\]
with \(i \notin I\), is non-zero.

In particular, Claim 6.2 implies that
\[
\nu_k := \text{ord}(\varphi^k(s)) \leq d - w_{\text{min}} \quad \text{and} \quad \omega_k := \lim_{s \to 0} \frac{\varphi^k(s)}{s^{k_w}} \in T_{(\tau,q)}^r(C \times \mathbb{C}^n).
\]

Proof of Claim 6.2. Since \(I \in V_{f^j_{\tau}}\) for all \(j \in L' = \{1, \ldots, k_L'\}\), the uniform local tameness of the family \(\{V(f^1_{\tau}, \ldots, f^{k_L'}_{\tau})\}_t\) tells us that if \((\tau, \q)\) is close enough to the origin, then there exist indices \(i_0, 1, \ldots, i_{0,k_L'} \notin I\) such that the determinant of the \((k_L' \times k_L')\)-matrix
\[
(6.4)
\begin{align*}
\begin{pmatrix}
\frac{\partial f^j_{\tau,w}}{\partial z_{i_0,j'}}(a) \\
\end{pmatrix}_{1 \leq j,j' \leq k_L'}
\end{align*}
\]
does not vanish. Indeed, pick a positive number \(R\) as in Definition 3.2 and choose \((\tau, \q)\) so small that a radius of local tameness of the set of functions \(\{f^1_{\tau}, \ldots, f^{k_L'}_{\tau}\}\) is greater than \(R\). Since \(\rho(s) \in S^J(L)\), the expression
\[
f^j(\rho(s)) = f^j_{\tau,w}(a) s^d + \ldots
\]
vanishes for any \(s\) and any \(1 \leq j \leq k_L'\). Clearly, this implies that \(a\) belongs to the toric variety
\[
V^*(f^1_{\tau,w}, \ldots, f^{k_L'}_{\tau,w}) \cap \mathbb{C}^n(q_1, \ldots, q_{n_I}),
\]
and since \(\mathbb{C}^I\) is a vanishing coordinate subspace for the functions \(f^1_{\tau}, \ldots, f^{k_L'}_{\tau}\), the local tameness condition says that this variety is a reduced, non-singular, complete intersection variety in \(\mathbb{C}^n(q_1, \ldots, q_{n_I})\). In particular, \(k_L' \leq n - n_I\) and
\[
df^1_{\tau,w}(a) \wedge \cdots \wedge df^{k_L'}_{\tau,w}(a) \neq 0.
\]
In other words,
\[
\sum_{n_1 < i_1 < \ldots < i_{k_L'} \leq n} \det \begin{pmatrix} \frac{\partial f^j_{\tau,w}}{\partial z_{i,j'}}(a) \end{pmatrix}_{1 \leq j,j' \leq k_L'} dz_{i_1} \wedge \cdots \wedge dz_{i_{k_L'}}, \neq 0.
\]
Therefore, there exist indices \(i_0, 1, \ldots, i_{0,k_L'} \notin I = \{1, \ldots, n_I\}\) such that the determinant of the matrix \((6.4)\) does not vanish as desired.

Now, since we can substitute \(\varphi^k(s)\) to \(df^k(\rho(s))\) in the expression
\[
df(\rho(s)) \wedge \cdots \wedge df^{k_L'}(\rho(s))
\]
without changing anything, by comparing the coefficients of \(dz_{i_0,1} \wedge \cdots \wedge dz_{i_0,k_L'}\) before and after the substitution, we get the property stated in Claim 6.2. \(\square\)
Second step. Now, pick $1 \leq k_1 \leq k_{L'}$ such that
\[ \text{ord } df^{k_1}(\rho(s)) = \min \{ \text{ord } df^k(\rho(s)) \mid 1 \leq k \leq k_{L'} \}, \]
and choose inductively $1 \leq k_j \leq k_{L'}$, $k_j \neq k_1, \ldots, k_{j-1}$, together with polynomials $c_{k_j,1}(s), \ldots, c_{k_j,j-1}(s)$ such that the order $\nu_{k_j}$ of
\[ \varphi^{k_j}(s) := df^{k_j}(\rho(s)) + \sum_{l=1}^{j-1} c_{k_j,l}(s) df^{k_l}(\rho(s)) \]
is equal to the relative order\(^2\) \[ \text{ord}(df^{k_j}(\rho(s)); \{k_1, \ldots, k_{j-1}\}) \text{ and} \]
\[ \text{ord}(df^{k_j}(\rho(s)); \{k_1, \ldots, k_{j-1}\} \mid k \neq k_1, \ldots, k_{j-1}). \]
Then, as $\varphi^{k_j}(s) = \omega_{k_j} s^{\nu_{k_j}} + \cdots$, we have $\nu_{k_1} \leq \cdots \leq \nu_{k_{L'}} \leq d - w_{\text{min}}$ and $\omega_{k_1}, \ldots, \omega_{k_{L'}}$ are linearly independent cotangent vectors in $T^*_\tau(q) (\mathbb{C} \times \mathbb{C}^n)$. The last assertion can be proved by induction as follows. Let us assume that $\omega_{k_1}, \ldots, \omega_{k_{j-1}}$ are linearly independent while $\omega_{k_1}, \ldots, \omega_{k_j}$ are not. Then there are constants $c_{k_1}, \ldots, c_{k_{j-1}}$ such that $\omega_{k_j} = \sum_{l=1}^{j-1} c_{k_j} \omega_{k_l}$. It follows that the order of
\[ \psi^{k_j}(s) := \varphi^{k_j}(s) - \sum_{l=1}^{j-1} c_{k_j} s^{\nu_{k_j} - \nu_{k_l}} \varphi^{k_l}(s) \]
is greater than $\nu_{k_j}$ and $\psi^{k_j}(s)$ is the sum of $df^{k_j}(\rho(s))$ with a linear combination (whose coefficients are polynomials in $s$) of $df^{k_1}(\rho(s)), \ldots, df^{k_{j-1}}(\rho(s))$. It follows that
\[ \nu_{k_j} < \text{ord } \psi^{k_j}(s) \leq \text{ord}(df^{k_j}(\rho(s)); \{k_1, \ldots, k_{j-1}\}) = \nu_{k_j}, \]
which is a contradiction. This completes the proof of Lemma 6.1. \qed

6.3. Construction of the forms $\omega_k$ corresponding to the functions $f^k$ such that $I \notin \mathcal{V}_{I^k}$. Let us now consider the set $L \setminus L' = \{k_{L'} + 1, \ldots, k_L\}$ of indices $k$ such that $I \notin \mathcal{V}_{I^k}$. Then we have the following lemma.

Lemma 6.3. For any $k_{L'} + 1 \leq k \leq k_L$, let us write
\[ df^k(\rho(s)) = \omega_k s^{w_k} + \cdots, \]
where $\omega_k \neq 0$. Then $\nu_k = 0$ and $\omega_{k_{L'} + 1}, \ldots, \omega_{k_L}$ are linearly independent cotangent vectors in $T^*_\tau(q) (\mathbb{C} \times \mathbb{C}^n)$.

---

\(^2\)The relative order, $\text{ord}(df^{k_j}(\rho(s)); \{k_1, \ldots, k_{j-1}\})$, of $df^{k_j}(\rho(s))$ modulo $\{k_1, \ldots, k_{j-1}\}$ is defined by
\[ \max \left\{ \text{ord} \left( df^{k_j}(\rho(s)) + \sum_{l=1}^{j-1} c_l(s) df^{k_l}(\rho(s)) \right) \mid c_l(s), \ldots, c_{j-1}(s) \in \mathbb{C}[s] \right\}. \]
Proof. For simplicity, we shall write \( f^k_\tau := f^k_{\tau|C} \). Since \( I \notin V_{f^k_\tau} \) for any \( k_{L'} + 1 \leq k \leq k_L \), we have \( d(\mathbf{w}; f^k_\tau) = 0 \) and \( f^k_{\tau,\mathbf{w}} = f^k_\tau \). Moreover, since \( \rho(s) \in S^f(L) \), the expression
\[
 f^k(\rho(s)) = f^k_{\tau,\mathbf{w}}(\mathbf{s}) s^0 + \cdots
\]
vanishes for any \( s \) and any \( k_{L'} + 1 \leq k \leq k_L \), so that \( \mathbf{q} \in V(f^k_{\tau,\mathbf{w}}) \) for all \( k_{L'} + 1 \leq k \leq k_L \). The non-degeneracy condition says that by shrinking \( (\tau, \mathbf{q}) \) one more time if necessary, the variety
\[
V(f^k_{\tau,\mathbf{w}}, \ldots, f^k_L)
\]
is a non-degenerate complete intersection variety, and hence,
\[
df^k_{\tau,\mathbf{w}}, \ldots, df^k_L
\]
is nowhere vanishing in \( V^*(f^k_{\tau,\mathbf{w}}, \ldots, f^k_L) \). Since for \( k_{L'} + 1 \leq k \leq k_L \), the functions \( f^k_{\tau,\mathbf{w}} \) involves only the variables \( z_1, \ldots, z_{n_1} \), it follows that \( k_L - k_{L'} \leq n_I \) and there are indices \( i_0, k_{L'}, \ldots, i_{n_1, k_L} \in I \) such that the determinant of the \(( (k_L - k_{L'}) \times (k_L - k_{L'}))\)-matrix
\[
\left( \frac{\partial f^k_{\tau,\mathbf{w}}}{\partial z_{i_0,k'}}(\mathbf{q}) \right)_{k_{L'}+1 \leq k,k' \leq k_L}
\]
does not vanish. This implies that \( \nu_k = 0 \). It also implies that \( \omega_{k_{L'}+1} \wedge \cdots \wedge \omega_{k_L} \) has a non-zero coefficient in \( dz_{i_0,k_{L'}+1} \wedge \cdots \wedge dz_{i_0,k_L} \), and hence \( \omega_{k_{L'}+1}, \ldots, \omega_{k_L} \) are linearly independent. \( \square \)

6.4. Consequence of Lemmas 6.1 and 6.3. It follows from these lemmas that \( \omega_1 \wedge \cdots \wedge \omega_{k_L} \wedge \omega_{k_{L'}+1} \wedge \cdots \wedge \omega_{k_L} \neq 0 \). Moreover, since
\[
\bigwedge_{k=1}^{k_L} df^k(\rho(s)) = \bigwedge_{k=1}^{k_{L'}} \varphi^k(s) \wedge \bigwedge_{k=k_{L'+1}}^{k_L} df^k(\rho(s)),
\]
where \( \varphi^k(s) \) is defined in (6.5), we deduce that \( \omega_{k_L} = \nu_1 + \cdots + \nu_{k_L} \) and \( \omega_\infty \) is decomposable equal to \( \omega_1 \wedge \cdots \wedge \omega_{k_L} \). Thus, as announced above, to prove that \( \ell_\infty \in \omega_\infty \), it suffices to show that \( \omega_k(\ell_\infty) = 0 \) for all \( 1 \leq k \leq k_L \). Indeed, \( \nu_\infty(\omega_\infty) = \nu_\infty(\omega_1 \wedge \cdots \wedge \omega_{k_L}) = 0 \) if and only if
\[
\sum_{k=1}^{k_L} (-1)^{k-1} \omega_k(\ell_\infty) \omega_1 \wedge \cdots \wedge \omega_{k-1} \wedge \omega_{k+1} \wedge \cdots \wedge \omega_{k_L} = 0.
\]
So, if \( \omega_k(\ell_\infty) = 0 \) for all \( 1 \leq k \leq k_L \), then \( \nu_\infty(\omega_\infty) = 0 \), that is, \( \ell_\infty \in \omega_\infty \).

6.5. Proof of the equality \( \omega_k(\ell_\infty) = 0 \) for \( 1 \leq k \leq k_{L'} \). By definition, if we put
\[
\omega_k := \omega_{k,0} dt + \sum_{i=1}^{n} \omega_{k,i} dz_i,
\]
then (6.2) is written as
\[
df^k(\rho(s)) + \sum_{l=1}^{k-1} c_{k,l}(s) df^l(\rho(s)) = \left( \omega_{k,0} dt + \sum_{i=1}^{n} \omega_{k,i} dz_i \right) s^{\rho_k} + \cdots.
\]
Applying both sides of this equality to the canonical basis of $\mathbb{C} \times \mathbb{C}^n$ shows that

$$
\left\{
\begin{align*}
\left( \frac{\partial f^k}{\partial t}(t_0, a) + \sum_{l=1}^{k-1} c_{k,l}(0) \frac{\partial f^l}{\partial t}(t_0, a) \right) s^d + \cdots + \omega_{k,0} s^{\nu_k} + \cdots , \\
\left( \frac{\partial f^k}{\partial z_i}(a) + \sum_{l=1}^{k-1} c_{k,l}(0) \frac{\partial f^l}{\partial z_i}(a) \right) s^{d-w_i} + \cdots + \omega_{k,i} s^{\nu_k} + \cdots .
\end{align*}
\right.
\tag{6.6}
$$

As $\nu_k \leq d - w_{\min} \leq d - 1$ (see Lemma 6.1), we must have $\omega_{k,0} = 0$. We must also have $\omega_{k,i} = 0$ for $1 \leq i \leq n_1$ as $w_i = 0$ within this range of indices.

**Remark 6.4.** This implies $\lim_{s \to 0} T_{\rho(s)} V^{s^j}(f^k) \supseteq \mathbb{C} \times \mathbb{C}^l$.

Now, since $\omega_{\ell} \leq w_{\min}$, the vector $\omega_{\ell} := (\ell_{\infty,0}, \ell_{\infty,1}, \ldots, \ell_{\infty,n})$ is of the form

$$
\omega_{\ell} = \omega_{\ell_{\infty,0}} \ell_{\infty,0} + \sum_{i=1}^{n_1} \omega_{\ell_{\infty,i}} \ell_{\infty,i} + \sum_{i=n_1+1}^{n} \omega_{\ell_{\infty,i}} \ell_{\infty,i} = 0.
\tag{6.7}
$$

If $\omega_{\ell} = w_{\min}$, then the proof divides into two cases:

1. $\nu_k < d - w_{\min}$;
2. $\nu_k = d - w_{\min}$.

In the first case, by $(6.6)$, we must have $\omega_{k,i} = 0$ not only for $0 \leq i \leq n_1$ but also for $n_1 + 1 \leq i \leq n_1 + m_I$, and hence

$$
\omega_{k}(\ell_{\infty}) = \omega_{k,0} \ell_{\infty,0} + \sum_{i=1}^{n_1+m_I} \omega_{k,i} \ell_{\infty,i} = 0,
$$

as desired. In the second case, we still have $\omega_{k,i} = 0$ for $0 \leq i \leq n_1$ but we do not know whether $\omega_{k,i} = 0$ for $n_1 + 1 \leq i \leq n_1 + m_I$. Thus, since $\ell_{\infty,i} = 0$ for $n_1 + m_I + 1 \leq i \leq n$, we have

$$
\omega_{k}(\ell_{\infty}) = \sum_{i=n_1+1}^{n_1+m_I} \omega_{k,i} \ell_{\infty,i} = \sum_{i=n_1+1}^{n_1+m_I} \omega_{k,i} a_i.
$$

Since $\rho(s) \in S^J(L)$, we have $f^l \circ \rho(s) = 0$, and hence $\frac{d(f^l \circ \rho)}{ds}(s) = 0$, for any $s$ and any $l \in L$. It follows that

$$
\left( df^k(\rho(s)) + \sum_{l=1}^{k-1} c_{k,l}(s) df^l(\rho(s)) \right) \left( \frac{d\rho}{ds}(s) \right) = \left( \omega_{k} s^{\nu_k} + \cdots \right) \left( \frac{d\rho}{ds}(s) \right) = 0
$$

for any $s$. Then, by taking the coefficient of the term with the lowest degree

(i.e., the coefficient of $s^{d-1}$), we obtain

$$
\sum_{i=n_1+1}^{n} \left( \frac{\partial f^k}{\partial z_i}(a) + \sum_{l=1}^{k-1} c_{k,l}(0) \frac{\partial f^l}{\partial z_i}(a) \right) a_i w_i = 0.
\tag{6.8}
$$
Thus (6.8) is simply written as
\[ w \sim \text{min} (0, 1) \] for \( n_I + 1 \leq i \leq n_I + m_I \);
\[ \frac{\partial f^k}{\partial z_i} (a) + \sum_{l=1}^{k-1} c_{k,l}(0) \frac{\partial f^l}{\partial z_i} (a) = 0 \text{ for } n_I + m_I + 1 \leq i \leq n. \]

Thus (6.8) is simply written as
\[ 0 = \sum_{i=n_I+1}^{n_I+m_I} \omega_{k,i} w_i = w_{\min} \sum_{i=n_I+1}^{n_I+m_I} \omega_{k,i} = w_{\min} \omega_k(\ell_{\infty}). \]

Since \( w_{\min} > 0 \), again we have \( \omega_k(\ell_{\infty}) = 0 \).

6.6. **Proof of the equality** \( \omega_k(\ell_{\infty}) = 0 \) for \( k_{L'} + 1 \leq k \leq k_L \). Since \( \rho(s) \in S^{(L)}(\mathbb{L}) \) and \( \rho'(s) \in S^{(L)}(\mathbb{K}) \), we have \( f^k(\rho(s)) = f^k(\rho'(s)) = 0 \) for all \( s \).

Then, by the Taylor formula applied to the function \( f^k \) at the point \( \rho(s) \), there is a constant \( c \in (0, 1) \) such that for any \( s \neq 0 \) small enough,
\[
0 = \frac{f^k(\rho'(s)) - f^k(\rho(s))}{|s|^{\omega}} = \sum_{i=0}^{n} \frac{\partial f^k}{\partial z_i}(\rho(s)) \frac{z_i'(s) - z_i(s)}{|s|^{\omega}} + \frac{1}{|s|^{\omega}} R(s),
\]
where
\[
\frac{1}{|s|^{\omega}} R(s) \leq \frac{c}{|s|^{\omega}} \| \rho'(s) - \rho(s) \|^{2} = \frac{c}{|s|^{\omega}} \| \ell(s) \|^{2}
\]
tends to 0 as \( s \to 0 \). (Here, to simplify, we have written \( z_0(s) \) and \( z_0'(s) \) instead of \( t(s) \) and \( t'(s) \).) It follows that
\[
df^k(\rho(s)) \begin{pmatrix} \ell(s) \\ |s|^{\omega} \end{pmatrix} = \sum_{i=0}^{n} \frac{\partial f^k}{\partial z_i}(\rho(s)) \begin{pmatrix} \ell_i(s) \\ |s|^{\omega} \end{pmatrix}
\]
tends to 0 as \( s \to 0 \), that is, \( \omega_k(\ell_{\infty}) = 0 \).

6.7. **Conclusion.** We have proved Theorem 5.3 if \( I \neq \emptyset \). Actually, the argument developed above still works if \( I = \emptyset \) and is even simpler. Indeed, in this case, \( 6.3 \) and \( 6.6 \) are no longer relevant, and since \( w \) is a positive weight vector, Lemma 6.1 just follows from the non-degeneracy of \( V(f_1, \ldots, f_{k_{L'}}) \) and the constancy of the Newton diagram; the uniform local tameness is no longer needed.

**Remark 6.5.** A straightforward modification of the proof shows that Theorem 3.3 extends to multi-parameter deformation families.

7. **Direct proof of Theorem 4.1**

We have seen in Section 4 that Theorem 4.1 can be obtained by combining Theorem 3.3—which asserts that \( S \) is Whitney (b)-regular—with a theorem of Parusinski [15] and Briançon–Maisonobe–Merle [2]—which says that Whitney (b)-regular stratifications always satisfy so-called \( w_f \) condition, and hence, Thom’s \( a_f \) condition. Theorem 4.1 can also be proved by a direct explicit calculation using only elementary methods. Hereafter we outline this argument.
By an appropriate version of [10] Proposition (2.2), to show that $S$ satisfies Thom’s $a_f$ condition, it suffices to prove that for any $I \subseteq \{1, \ldots, n\}$, any $K \subseteq K_0$, any $(\tau, q) = (\tau, q_1, \ldots, q_n) \in S^f(K)$ close enough to the origin, and any real analytic path $\rho(s) = ([t(s), z(s)])$ with $\rho(0) = (\tau, q)$ and $\rho(s) \notin V(f)$ for $s \neq 0$, the following condition on the tangent spaces holds true:

$$
\lim_{s \to 0} T_{\rho(s)}V(f - f(\rho(s))) \supseteq T_{(\tau, q)}S^f(K).
$$

To simplify, as in the proof of Theorem 3.3 we shall assume $\emptyset \neq I = \{1, \ldots, n\}$. Then we divide the argument into two cases. First, we consider the case where $K = K_0$, $I \neq V_{f_k}$ for $1 \leq k \leq k_0$ and $I \in V_{f_k}$ for $k_0 + 1 \leq k \leq k_0$. Then, without loss of generality, we may suppose that

$$
\begin{cases}
f_{\tau, w}(a) = 0 & \text{for } k_0' + 1 \leq k \leq k_0'' \leq k_0, \\
f_{\tau, w}(a) \neq 0 & \text{for } 0 \leq k' \leq k_0', \\
\end{cases}
$$

where, as above, $a := (a_1, \ldots, a_n)$ and $w := (w_1, \ldots, w_n)$ are defined by the Taylor expansions $z_i(s) = a_i s^{w_i} + \cdots$ ($1 \leq i \leq n$). Put $h := f_k'' \cdots f_{k_0}' f_{k_0}' \cdots f_k' h$ and decompose $f$ as

$$
f = (f^1 \cdots f_{k_0}^0) \cdot (f_{k_0}^0 \cdots f_{k_0}^{k_0''}) \cdot h.
$$

By the proof of Proposition 3.2 in [13], for any $s \neq 0$, the tangent space $T_{\rho(s)}V(f - f(\rho(s)))$ contains the intersection

$$
\left( \bigcap_{k=1}^{k_0} T_{\rho(s)}V(f_k - f_k(\rho(s))) \right) \cap T_{\rho(s)}V(f_{k_0}' \cdots f_{k_0}'' \cdot h - f_{k_0}' \cdots f_{k_0}'' \cdot h(\rho(s))).
$$

By the non-degeneracy condition, $V^{\mathbb{C}}(f^k)$ is non-singular for any $1 \leq k \leq k_0''$ (see [11] Chap. V, Lemma (2.8.2)), and since $V^{\mathbb{C}}(f^k) = V(f^k) \cap (\mathbb{C} \times \mathbb{C}^n) \ni (\tau, q)$ is a non-singular open subset of $V(f^k)$, the point $(\tau, q)$ is a non-singular point of $V(f^k)$. Thus, for any $1 \leq k \leq k_0'$, we have

$$
\lim_{s \to 0} T_{\rho(s)}V(f_k - f_k(\rho(s))) = T_{(\tau, q)}V(f^k) \supseteq T_{(\tau, q)}V^{\mathbb{C}}(f^k).
$$

The uniform local tameness of the family $\{V(f^k_{l_0}' \cdots f^k_{l_0}'')\}_l$ says that if $(\tau, q)$ is close enough to the origin, then

$$
W := V(f^k_{l_0}' \cdots f^k_{l_0}'', \ldots, f^k_{l_0}' \cdots f^k_{l_0}'') \cap \mathbb{C}^n(q_1, \ldots, q_n)
$$

is a reduced, non-singular, complete intersection variety in $\mathbb{C}^n(q_1, \ldots, q_n)$. In particular, since $a$ lies in $W$,

$$
df_{\tau, w}(a) \wedge \cdots \wedge df^{k_0''}_{\tau, w}(a) \neq 0.
$$

Now, since $h_{\tau, w} = f^k_{l_0}' \cdots f^k_{l_0}''$ is weighted homogeneous and $W$ is invariant under the associated $\mathbb{C}^*$-action on $\mathbb{C}^n(q_1, \ldots, q_n)$, the restriction of $h_{\tau, w}$ to $W$ may only have zero as critical value. Since $h_{\tau, w}(a) \neq 0$, it follows that $dh_{\tau, w}(a) \neq 0$, and hence

$$
\lim_{s \to 0} T_{\rho(s)}V(f_{\tau, w} - f_{\rho(s)}(\rho(s))) \supseteq T_{(\tau, q, W)}V_{\tau, w}^{\mathbb{C}}(f_{\tau, w}).
$$
are linearly independent. Then, by an argument similar to that given in (6.2) the normalized limit of
\[ df^{k+1}(\rho(s)) \wedge \cdots \wedge df^0(\rho(s)) \wedge dh(\rho(s)) \]
as \( s \to 0 \) is a decomposable form in \( \mathbb{C}^n(q_1, \ldots, q_n) \), and
\[ (7.4) \lim_{s \to 0} T_{\rho(s)}V(f^0 \cdots f^0 \cdot h - f^0 \cdots f^0 \cdot h(\rho(s))) \supseteq \mathbb{C} \times \mathbb{C}^l. \]

Combining (7.2) and (7.4) show that
\[ \lim_{s \to 0} T_{\rho(s)}V(f - f(\rho(s))) \supseteq \left( \bigcap_{1 \leq k \leq k_0} T_{(\tau, q)}V^{*l}(f^k) \right) \cap (\mathbb{C} \times \mathbb{C}^l) \supseteq T_{(\tau, q)}S^l(K). \]

Now, we look at the case where \( K \subseteq K_0 \). To simplify, we assume \( K = \{1, \ldots, kK\} \), \( I \notin V_{f^k} \) for \( 1 \leq k \leq k'_K \leq k_K \) (this range is empty if \( I \in V_{f^k} \) for all \( k \in K \)) and for \( k_K + 1 \leq k \leq k_0 \), and \( I \notin V_{f^k} \) for all the other values of \( k \). (Note that for \( k_K + 1 \leq k \leq k_0 \), the relation \( I \notin V_{f^k} \) is always true by definition of \( S^l(K) \).) Then we have the following properties.

1. For \( 1 \leq k \leq k'_K \) (again this range may be empty), the non-degeneracy condition shows that \( V^{*l}(f^k) \) is non-singular and \( (\tau, q) \) is a non-singular point of \( V(f^k) \). Thus, for all such \( k \)'s, we have:
\[ \lim_{s \to 0} T_{\rho(s)}V(f^k - f^k(\rho(s))) = T_{(\tau, q)}V(f^k) \supseteq T_{(\tau, q)}V^{*l}(f^k). \]

2. Assume that \( k'_K \geq 1 \). Since \( (\tau, q) \in S^l(K) \), we have \( f^{k_K}(\tau, q) = 0 \) while \( f^k(\tau, q) \neq 0 \) for \( k_K + 1 \leq k \leq k_0 \). By the non-degeneracy condition, \( V^{*l}(f^{k_K}) \) is non-singular and \( (\tau, q) \) is a non-singular point of \( V(f^{k_K}) \), and hence, a non-singular point of \( V(g) \), where \( g := f^{k_K}f^{k_K+1} \cdots f^{k_0} \). Thus,
\[ \lim_{s \to 0} T_{\rho(s)}V(g - g(\rho(s))) = T_{(\tau, q)}V(g) = T_{(\tau, q)}V(f^{k_K}) \supseteq T_{(\tau, q)}V^{*l}(f^{k_K}). \]

3. For \( k_K + 1 \leq k \leq k_K \), let us assume (to simplify) that
\[ \begin{cases} f^k_{\tau, \omega}(a) = 0 \text{ for } k'_K + 1 \leq k \leq k''_K \leq k_K, \\ f^k_{\tau, \omega}(a) \neq 0 \text{ for } k''_K + 1 \leq k \leq k_K. \end{cases} \]

Then, as in (7.3) and (7.4), writing \( u := f^{k_K+1} \cdots f^{k_K} \) and using the uniform local tameness condition, we show that
\[ du_{\tau, \omega}(a), df^{k_K+1}_{\tau, \omega}(a), \ldots, df^{k_K}_{\tau, \omega}(a) \]
are linearly independent, and hence
\[ \lim_{s \to 0} T_{\rho(s)}V(f^{k_K+1} \cdots f^{k_K} \cdot u - f^{k_K+1} \cdots f^{k_K} \cdot u(\rho(s))) \supseteq \mathbb{C} \times \mathbb{C}^l. \]

Combined with the proof of Proposition 3.2 in [13] again, properties (1)–(3) show that if \( k'_K \geq 1 \), then
\[ \lim_{s \to 0} T_{\rho(s)}V(f - f(\rho(s))) \supseteq T_{(\tau, q)}S^l(K). \]
To complete the proof, it remains to consider the case where $I \in V_{f_k}$ for all $1 \leq k \leq k_K$ (i.e., by abuse of language, the case where $k'_K = 0$). By reordering, we may assume that

$$\text{ord } f_{kK}(\rho(s)) = \min\{\text{ord } f_k(\rho(s)) \mid 1 \leq k \leq k_K\}.$$ 

Put $p := f_{kK} \cdot f_{kK+1} \cdots f_{k0}$. Since

$$p_{\tau,w} = f_{kK} \cdot \prod_{k=kK+1}^{k0} (f_k(\tau_c))$$

(see the proof of Lemma 6.3), it follows from the uniform local tameness condition that if $(\tau, q)$ is close enough to the origin, then

$$V(f^1_{\tau,w}, \ldots, f^{kK-1}_{\tau,w}, p_{\tau,w}) \cap \mathbb{C}^{\tau n}(q_1, \ldots, q_{n_t})$$

is a reduced, non-singular, complete intersection variety in $\mathbb{C}^{\tau n}(q_1, \ldots, q_{n_t})$. Then, by an argument similar to that given in §6.2 again, we show that the normalized limit of

$$df^1(\rho(s)) \wedge \cdots \wedge df^{kK-1}(\rho(s)) \wedge dp(\rho(s))$$

as $s \to 0$ is decomposable in $\mathbb{C}^{\tau n}(q_1, \ldots, q_{n_t})$, and

$$\lim_{s \to 0} T_{\rho(s)} V(f - f(\rho(s))) \supseteq \mathbb{C} \times C^I = T_{(\tau, q)} S^I(K).$$

8. PROOF OF PROPOSITION 6.2

We argue by contradiction. If the assertion fails, then (using the curve selection lemma) there is a real analytic path $\rho(s) = (t(s), z(s))$ such that $\rho(0) = (0, 0)$ and $df(\rho(s)) \equiv 0$. We may assume that $z(s) \in \mathbb{C}^{\tau n}$ for $s \neq 0$. Consider the Taylor expansions

$$t(s) = t_0 s^{w_0} + \cdots$$
$$z_i(s) = a_i s^{w_i} + \cdots (1 \leq i \leq n),$$

where $t_0$, $a_i \neq 0$ and $w_0, w_i > 0$, and set $a := (a_1, \ldots, a_n)$, $w := (w_1, \ldots, w_n)$ and $\bar{w} := (w_0, w_1, \ldots, w_n)$. Note that $d(\bar{w}; f^k) = d(w; f^k_0)$, and since $w_0 > 0$, $f^k_0(t, z) = f^k_0(w(z))$ for all $1 \leq k \leq k_0$. For simplicity, we assume that

$$\begin{cases}
    f^k_{0,w}(a) = 0 & \text{for } 1 \leq k \leq k'_0 \leq k_0, \\
    f^k_{0,w}(a) \neq 0 & \text{for } k'_0 + 1 \leq k \leq k_0.
\end{cases}$$

Let $d_k := d(w; f^k)$. Then we have

$$f^k(\rho(s)) = f^k_{0,w}(a) s^{d_k} + \cdots$$

and

$$\frac{\partial f^k}{\partial z_i}(\rho(s)) = \frac{\partial f^k_{0,w}}{\partial z_i}(a) s^{d_k-w_i} + \cdots.$$ 

Suppose that $k'_0 \leq k_0-1$ and write $f = f^1 \cdots f^{k_0-1} \cdot h$, where $h := f^{k'_0+1} \cdots f^{k_0}$. Then we have

$$\frac{\partial f}{\partial z_i}(\rho(s)) = \sum_{k=1}^{k'_0} \left( \frac{\partial f^k}{\partial z_i}(\rho(s)) \cdot h(\rho(s)) \cdot \prod_{1 \leq k' \leq k'_0 \mid k' \neq k} f^{k'}(\rho(s)) \right) + \frac{\partial h}{\partial z_i}(\rho(s)) \cdot \prod_{k=1}^{k'_0} f^k(\rho(s)).$$
To simplify, put

\[ A_i^k(s) := \left( \frac{\partial f^k}{\partial z_i}(\rho(s)) \cdot h(\rho(s)) \cdot \prod_{1 \leq l \leq k', k \neq k'} f^{k'}(\rho(s)) \right) \] and \[ B_i(s) := \frac{\partial h}{\partial z_i}(\rho(s)) \cdot \prod_{k=1}^{k_0'} f^k(\rho(s)). \]

If \( d_k' \) denotes the order (in \( s \)) of \( f^k(\rho(s)) \), then

\[ \text{(8.1) ord} A_i^k(s) \geq d_k - w_i + \sum_{k'=1}^{k_0'} d_{k'} - d_k' + d(\mathbf{w}; h_0). \]

(Note that, as above, \( d(\mathbf{w}; h) = d(\mathbf{w}; h_0) \) and \( h_\mathbf{w}(t, \mathbf{z}) = h_{0, \mathbf{w}}(\mathbf{z}). \) Let \( e_k := d_k + \sum_{k'=1}^{k_0'} d_{k'} - d_k' \), and for simplicity assume that \( e_{\min} := e_1 = \cdots = e_{k_0'} < e_{k_0'} + 1 \leq \cdots \leq e_{k_0}. \)

Then, \( \text{[S1]} \) is written as ord \( A_i^k(s) \geq d(\mathbf{w}; h_0) - w_i \), and since \( d_k' > d_k \), we also have

\[ \text{(8.2) ord} B_i(s) \geq d(\mathbf{w}; h_0) - w_i + \sum_{k'=1}^{k_0'} d_{k'} > d(\mathbf{w}; h_0) - w_i + e_k. \]

Now, since \( \mathbf{a} \in V^*(f_0^1, \ldots, f_0^{k_0'}) \) and \( V(f_0^1, \ldots, f_0^{k_0''}) \) is a non-degenerate complete intersection variety, we must have

\[ \text{(8.3) } df_0^1(\mathbf{a}) \wedge \cdots \wedge df_0^{k''}(\mathbf{a}) \neq 0, \]

and therefore there exist \( i_1, \ldots, i_{k''} \) such that the determinant of the matrix

\[ \left( \frac{\partial f^k_{i_0, \mathbf{w}}(\mathbf{a})}{\partial z_{i_j}} \right)_{1 \leq i, j \leq k''} \]

is non-zero. In particular, for all \( i_j \in \{i_1, \ldots, i_{k''}\} \) there is at least an index \( k_{i_j} \) such that

\[ \text{(8.4) } \frac{\partial f_{i_0, \mathbf{w}}^{k_{i_j}}(\mathbf{a})}{\partial z_{i_j}} \neq 0. \]

Let \( m := \min\{d(\mathbf{w}; h_0) - w_{i_j} + e_{\min} \mid 1 \leq j \leq k''\} \). Then we easily check that there exist non-zero complex numbers \( c_1, \ldots, c_{k''} \) such that for any \( i_j \in \{i_1, \ldots, i_{k''}\} \) we have

\[ \frac{\partial f}{\partial z_{i_j}}(\rho(s)) = \sum_{k=1}^{k''} D_k s^m + \cdots, \]

where

\[ D_k := \begin{cases} \frac{\partial f_{i_0, \mathbf{w}}^{k_{i_j}}(\mathbf{a})}{\partial z_{i_j}} \cdot c_k & \text{if } d(\mathbf{w}; h_0) - w_{i_j} + e_{\min} = m, \\ 0 & \text{if } d(\mathbf{w}; h_0) - w_{i_j} + e_{\min} > m. \end{cases} \]
Using (8.5), it is easy to see that there is at least an index \( i_0 \in \{ i_1, \ldots, i_{k'_0} \} \) and a non-empty subset \( E \subseteq \{ 1, \ldots, k'_0 \} \) such that

\[
(8.6) \quad \frac{\partial f}{\partial z_{i_0}}(\rho(s)) = \sum_{k \in E} \frac{\partial f_k}{\partial z_{i_0}}(a) \cdot c_k \cdot s^m + \cdots,
\]

with \( \frac{\partial f_k}{\partial z_{i_0}}(a) \neq 0 \). So, if \( df(\rho(s)) = 0 \), then the relation (8.6) vanishes and gives a linear relation between the elements of the set

\[
\left\{ \frac{\partial f_k}{\partial z_{i_0}}(a) \right\}_{k \in E}.
\]

This implies that the determinant of the matrix (8.5) vanishes—a contradiction to the Newton-admissibility condition.

The case \( k'_0 = k_0 \) can be proved exactly in the same way. If \( k'_0 = 0 \) (i.e., if \( f_k(a) \neq 0 \) for \( 1 \leq k \leq k_0 \)), then \( f_k(t, z) = h_k(t, z) \) is a weighted homogeneous polynomial and the assertion is obvious in this case.

Remark 8.1. In the above proof, we have only used the non-degeneracy condition. The uniform local tameness assumption is not needed.

9. Proof of Proposition 5.2

The argument is similar to that given in the proof of Corollary (2.8.1) in [11]. For completeness and convenience of the reader, we briefly recall and adapt it to our setting. We argue by contradiction. Choose a neighbourhood \( \tilde{D}_r \times \tilde{B}_r \) of the origin of \( \mathbb{C} \times \mathbb{C}^n \) such that Theorem 3.3 and Corollary 3.4 hold, and suppose there exist a sequence \( \{(t_m, z_m)\}_m \) converging to \((t_0, 0) \in \tilde{D}_r \times \tilde{B}_r \) and a stratum \( S := S^1(K) \in S \) such that \( \{t_m\} \times S_{\|z_m\|} \) is not transverse to \( \{(t_m) \times \mathbb{C}^n\} \cap S \) at \((t_m, z_m)\), that is,

\[
(9.1) \quad T_{(t_m, z_m)}(\{(t_m) \times \mathbb{C}^n\} \cap S) \subseteq T_{(t_m, z_m)}(\{t_m\} \times S_{\|z_m\|}) \subseteq \{t_m\} \times z_m^\perp,
\]

where \( z_m^\perp \) denotes the real orthogonal complement of \( z_m \). By compactness, taking a subsequence if necessary, we may assume that the line defined by \( z_m \) and the origin in \( \mathbb{C}^n \) converges to some \( \ell \) in \( \mathbb{P}^{n-1} \) and the following limits exist (in the appropriate Grassmannians):

\[
\cdot \quad T := \lim_{m \to \infty} T_{(t_m, z_m)}(\{(t_m) \times \mathbb{C}^n\} \cap S);
\]

\[
\cdot \quad T' := \lim_{m \to \infty} T_{(t_m, z_m)} S.
\]

By (9.1), \( T \subseteq \ell^\perp \). In particular, \( \ell \not\subseteq T \). Now, by the Whitney \((a)\)-regularity condition, we must have

\[
(9.2) \quad T' \supseteq T_{(t_0, 0)}(\mathbb{C} \times \{0\}),
\]

and since the line defined by \((t_m, z_m)\) and \((t_m, 0)\) in \( \mathbb{C} \times \mathbb{C}^n \) converges to \( \ell \) in \( \mathbb{P}^n \), the Whitney \((b)\)-regularity condition implies

\[
(9.3) \quad \ell \subseteq T'.
\]

Combined with the relation \( T' \supseteq T \), the inclusions (9.2) and (9.3) show that \( T' \) contains the subspace \( M \) generated by \( \ell \), \( T_{(t_0, 0)}(\mathbb{C} \times \{0\}) \) and \( T \).
Therefore,
\[ n + 1 - k = \dim T' \geq \dim M = 1 + 1 + (n - k) \]

\((k\) is the number of defining equations of the stratum \(S := S^I(K)\)), which is a contradiction.

10. Proof of Theorem 5.1

Again, we argue by contradiction. Choose \(\tau, r > 0\) so that Theorem 4.1 Propositions 4.2, 5.2, and Corollary 4.3 hold, and suppose that the family \(\{f_t\}\) does not have a uniform stable radius. Then, for all \(0 < \tau' \leq \tau\) and all \(0 < r' \leq r\), there exist \(0 < \varepsilon' \leq \varepsilon \leq r'\) such that for all sufficiently small \(\delta > 0\) there exist \(\eta_{\delta}, \varepsilon_{\delta}\) and \(t_{\delta}\), with \(0 < |\eta_{\delta}| \leq \delta, \varepsilon_{\delta} \leq \varepsilon \leq \varepsilon_{\delta}\) and \(|t_{\delta}| \leq r'\), such that \(V(f_{t_{\delta}} - \eta_{\delta})\) is non-singular in \(\tilde{B}_{\tau'}\) and does not transversely intersect the sphere \(S_{\varepsilon_{\delta}}\) at some point \(z_{\delta}\), so that

\[
T_{z_{\delta}} V(f_{t_{\delta}} - \eta_{\delta}) \subseteq T_{z_{\delta}} S_{\varepsilon_{\delta}} = T_{z_{\delta}} S_{||z_{\delta}||}. 
\]

Take \(\delta := \delta_m := 1/m\) and consider the corresponding sequence \(\{(t_{\delta_m}, z_{\delta_m})\}_m\) in \(D_{r'} \times (B_\varepsilon \setminus \tilde{B}_{\varepsilon'})\). By compactness, we may assume the following limits exist:

\[
\bullet \ T := \lim_{m \to \infty} T_{z_{\delta_m}} V(f_{t_{\delta_m}} - \eta_{\delta_m}); \\
\bullet \ T' := \lim_{m \to \infty} T_{(t_{\delta_m}, z_{\delta_m})} V(f - \eta_{\delta_m}); \\
\bullet \ (t_0, z_0) := \lim_{m \to \infty} (t_{\delta_m}, z_{\delta_m}) \in D_{r'} \times (B_\varepsilon \setminus \tilde{B}_{\varepsilon'}). 
\]

Then, by (10.1), we have:

\[
T \subseteq \lim_{m \to \infty} T_{z_{\delta_m}} S_{||z_{\delta_m}||} = T_{z_0} S_{||z_0||}.
\]

Let \(S_0\) be the stratum of \(S\) that contains \((t_0, z_0)\), and let \(S_0 := (\{t_0\} \times \mathbb{C}^n) \cap S_0\) be the stratum of \(S_0\) that contains \(z_0\) (in particular, \(\{t_0\} \times \mathbb{C}^n\) and \(S_0\) transversely intersect at \((t_0, z_0)\)). By Thom’s af condition, \(T_{(t_0, z_0)} S_0 \subseteq T'\), and hence

\[
T_{(t_0, z_0)} S_0 \subseteq (\{t_0\} \times \mathbb{C}^n) \cap T'. 
\]

This implies that \(\{t_0\} \times \mathbb{C}^n\) and \(T'\) transversely intersect at \((t_0, z_0)\) (as otherwise \(\{t_0\} \times \mathbb{C}^n\) and \(S_0\) would not be transverse at \((t_0, z_0)\) either). By taking the limit as \(m \to \infty\) of the expression

\[
\{t_{\delta_m}\} \times T_{z_{\delta_m}} V(f_{t_{\delta_m}} - \eta_{\delta_m}) \equiv T_{(t_{\delta_m}, z_{\delta_m})}(\{t_{\delta_m}\} \times V(f_{t_{\delta_m}} - \eta_{\delta_m})) = (\{t_{\delta_m}\} \times \mathbb{C}^n) \cap T_{(t_{\delta_m}, z_{\delta_m})} V(f - \eta_{\delta_m}),
\]

the transversality of \(\{t_0\} \times \mathbb{C}^n\) and \(T'\) at \((t_0, z_0)\) implies

\[
\{t_0\} \times T = (\{t_0\} \times \mathbb{C}^n) \cap T'. 
\]

Combined with (10.2) and (10.3), this shows

\[
T_{z_0} S_0 \equiv T_{(t_0, z_0)} S_0 \subseteq (\{t_0\} \times \mathbb{C}^n) \cap T' = \{t_0\} \times T \subseteq \{t_0\} \times T_{z_0} S_{||z_0||} \equiv T_{z_0} S_{||z_0||},
\]

and therefore \(S_0\) and \(S_{||z_0||}\) do not meet tranversely at \(z_0\), which contradicts Proposition 5.2.
