We consider a gas of \( N \) solitons for the Focusing Nonlinear Schrödinger (FNLS) equation in the limit \( N \to \infty \) with a point spectrum chosen to interpolate a given spectral soliton density over a domain of the complex spectral plane. We call this class of initial data, deterministic soliton gas. We show that when the domain is a disc and the soliton density is an analytic function, then the corresponding deterministic soliton gas surprisingly yields the one-soliton solution with point spectrum the center of the disc. We call this effect soliton shielding. When the domain is an ellipse, the soliton shielding reduces the spectral data to the soliton density concentrating between the foci of the ellipse. The physical solution is asymptotically step-like oscillatory, namely, the initial profile is a periodic elliptic function in the negative \( x \)-direction while it vanishes exponentially fast in the opposite direction.

Introduction. The wave propagation in a variety of physical systems is well described by dispersive integrable nonlinear wave equations. Integrability implies the existence of nonlinear modes that interact elastically and are called solitons. The inverse scattering, also called nonlinear Fourier transform, is the tool to analyze how a general given wave packet can be viewed as a nonlinear superposition of solitons. Recently several investigations, both on the mathematical and the physical side, have been carried out in which a very large number of solitons is considered. Coherent nonlinear superposition of many solitons occurs when one tries to optimally correlate the parameters of many nonlinear modes in order to produce a “macroscopic” wave profile that behaves more like a single broad wave packet than a combination of many smaller objects. This typically occurs in small dispersion limit or semiclassical limits.4,10. Incoherent/random nonlinear superpositions of solitons are more closely related to the notion of a soliton gas in an infinite statistical ensemble of interacting solitons that was first introduced by Zakharov12 for the Korteweg de Vries (KdV) equation. Further generalization were later derived for KdV (see e.g.3) and for the Focusing Nonlinear Schrödinger equation (FNLS) in 21. Statistical properties of solutions of large set of random solitons have been numerically investigated in 19,21,12,13,21. In this note, following the lines of 13, we consider a deterministic infinite set of solitons which we call deterministic soliton gas for the FNLS equation

\[
iv_t + \frac{1}{2} \psi_{xx} + |\psi|^2 \psi = 0. \tag{1}
\]

The one–soliton solution is given by

\[
\psi(x, t) = 2ib \text{sech}[2b(x + 2at - x_0)]e^{-2i[ax + (a^2 - b^2)t]} e^{i\phi_0} \tag{2}
\]

where \( x_0 \) is the initial peak position of the soliton, \( \phi_0 \) is the initial phase, \( 2b \) is the modulus of the wave maximal amplitude and \(-4a\) is the soliton velocity. The general \( N \) soliton solution is obtained from the Zakharov-Shabat linear spectral problem reformulated as a Riemann-Hilbert Problem (RHP) for a 2 \times 2 matrix \( Y^N(z; x, t) \), with the following data: the discrete spectrum \( S := \{ z_0; \ldots; z_N; z_1; \ldots; z_{N-1} \} \), \( z_j \in \mathbb{C}^+ \) the upper half space, and its norming constants \( \{ c_0, \ldots, c_{N-1} \} \) with \( c_j \in \mathbb{C} \).

The matrix \( Y^N(z; x, t) \) is analytic for \( z \in \mathbb{C} \backslash S \) and has simple poles in \( S \) with the residue condition

\[
\text{Res}_{z=z_j} Y^N(z) = \lim_{z \to z_j} Y^N(z) = \frac{0}{c_j e^{2b(z,x,t)} 0} \tag{3}
\]

\[
Y^N(z) = I + \mathcal{O}\left(\frac{1}{z}\right), \text{ as } z \to \infty,
\]

where \( \theta(z, x, t) = i(z^2 t + xz) \) and \( I \) is the identity matrix. Equations (3) uniquely determine \( Y^N(z; x, t) \). The solution of the FNLS equation is recovered from \( Y^N(z; x, t) \) by the relation

\[
\psi(x, t) = 2i \lim_{z \to \infty} z(Y^N(z; x, t))_{12}.
\]

In the case of one soliton solution, we have that the point spectrum \( z_0 = a + ib \) determines the speed and amplitude of the soliton (2) and the coefficient \( c_0 \) determines the position \( x_0 = \frac{\ln(|c_0|) - \ln(2b)}{2b} \) of the soliton peak and the phase \( \phi_0 = \arg(c_0) \) of the soliton. The FNLS equation can have a soliton of order \( N \) when the matrix function \( Y^N(z) \) has a pole of order \( N \). Such solution can be viewed as \( N \) pole solutions where the simple poles coalesce to a pole of order \( N \). The limit as \( N \to \infty \) of such solution has been studied in 21 where it has been shown that its far field structure is described by the Painlevé III equation.

In this letter we consider the case when the norming constants \( \{ c_j \}_{j=0}^{N-1} \) scale as \( 1/N \) as the number \( N \) of simple poles (i.e. the number of solitons) tends to infinity. Differently from 12 where the deterministic infinite set of solitons is obtained by letting the soliton spectra
accumulate on lines of the spectral complex plane, here we consider the case in which soliton spectra accumulate on one or more simply connected domains $D$ of the complex upper plane $\mathbb{C}^+$ and their complex conjugate $\overline{D}$. Our assumption on the distribution of the $z_j$’s and the value of the normalizing constants $c_j$ is that the measure $N^{-1} \sum c_j \delta_{z_j}$ tends in the limit $N \to \infty$ (in the sense of measures) to the measure

$$\mathrm{d}\mu = \beta(z, \overline{z}) \chi_D(z) \mathrm{d}^2z, \quad \mathrm{d}^2z = \frac{\mathrm{d}z \wedge \mathrm{d}\bar{z}}{2i}, \quad (4)$$

with $\chi_D$ the characteristic function of the domain $D$ and with a smooth density function $\beta(z, \overline{z})$. The limiting matrix function $Y(z; x, t)$ turns out to satisfy a $\partial$-problem.

The remarkable emerging feature is that for certain types of domains and densities, we have a “soliton shielding”, namely, the gas behaves as a finite number of solitons. This happens for example if the distribution function is $\beta(z, \overline{z}) = \pi^{-1/2} r(z)$ with $r(z)$ an analytic function in $D$, and the domain is described by $D := \{ z \in \mathbb{C} \text{ s.t. } |z|^m - z_0 | < \rho \}$, $m \in \mathbb{N}$, where $|z_0| > 0$ and $\rho > 0$ is sufficiently small so that $D$ lies in the upper half space. Then the deterministic soliton gas is equivalent to a $n$-soliton solution provided that $m = n$. In the case $m = 1$, the domain $D$ is a disc centered at $z_0$ and the corresponding soliton gas coagulates in a one-soliton solution with point spectrum $\{ z_0, \overline{z_0} \}$ and norming constant equal to $r^2(z_0)$ when $\beta(z, \overline{z}) = r(z)$ or with an $n$-order one soliton when $\beta(z, \overline{z}) = \pi^{-1/2} r(z)$, $n > 1$.

When the domain $D$ is an ellipse we show that such deterministic soliton gas solution is equivalent to a gas of solitons distributed on two segments connecting the foci of the ellipses. The initial data obtained in this way is a periodic elliptic wave at $x = -\infty$ and rapidly decreasing at $x = +\infty$ as in [13].

**Deterministic soliton gas.** In order to obtain the limit of the $N$-soliton solution as $N \to \infty$ we first rescale the norming constants $c_j$ to $c_j/N$. Using a transformation that removes the singularities of $Y^N$, we can rewrite the residue condition (4) as a RHP with jumps on a closed clockwise oriented contour $\gamma_+$ that encircles all poles in the upper half space and similarly $\gamma_- = \overline{\gamma_+}$ encircles all the poles in the lower half space. One ends up with the following RHP for the matrix function $\tilde{Y}^N(z; x, t)$

$$\tilde{Y}^N(z; x, t) = \tilde{Y}^N(z; x, t) \tilde{J}_N(z; x, t), \quad \tilde{J}_N(z; x, t) = \left( \begin{array}{c|c} 1 & \sum_{j=1}^{N} \frac{c_j e^{-2\theta(x, t)} z_j}{z - z_j} \chi_{\gamma_-} \\ \hline \frac{1}{N} \sum_{j=1}^{N} \frac{c_j e^{-2\theta(x, t)} z_j}{z - z_j} \chi_{\gamma_+} & 1 \end{array} \right)$$

$$\tilde{Y}^N(z; x, t) = I + O\left( \frac{1}{z} \right), \quad \text{as } z \to \infty,$$

where $\chi_{\gamma_{\pm}}$ are the characteristic functions of the curves $\gamma_{\pm}$, respectively. We call the matrix $\tilde{J}_N(z, x, t)$ the \textit{jump matrix}. Let $D$ be the domain bounded by $\gamma_+$, so that $\overline{D}$ is bounded by $\gamma_-$. We let the number $N$ of solitons tend to infinity in such a way that the measure $N^{-1} \sum c_j \delta_{z_j}$ tends to the measure (4). Thus

$$\sum_{j=1}^{N} \frac{c_j}{\pi(z - z_j)} \int_{D} \beta^*(w, \overline{w}) \mathrm{d}^2w / \pi.$$

Consequently the jump matrix of (5) becomes

$$\left( \begin{array}{c|c} 1 & \int_{D} \frac{e^{-2\theta(x, t)} \beta^*(w, \overline{w}) \mathrm{d}^2w}{\pi(z - w)} \chi_{\gamma_-} \\ \hline - \int_{D} \frac{e^{-2\theta(x, t)} \beta^*(w, \overline{w}) \mathrm{d}^2w}{\pi(z - w)} \chi_{\gamma_+} & 1 \end{array} \right).$$

Next we apply the $\partial$ operator to (7) and get

$$\begin{cases} \partial \Gamma(z, \overline{z}) = \Gamma(z, \overline{z}) e^{-\theta(x, t) \sigma_3} M_0(z, \overline{z}) e^{\theta(x, t) \sigma_3} \\ \Gamma(\infty) = I \end{cases}$$

with $\sigma_3 = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}$, and

$$M_0(z, \overline{z}) := \begin{pmatrix} 0 & \beta^*(z, \overline{z}) \chi_D \chi_{\gamma_-} \\ -\beta(z, \overline{z}) \chi_D & 0 \end{pmatrix}.$$
Then, by using the Cauchy-Plemelj formula we reduce the \( \partial D \)-problem to the integral equation
\[
\begin{align*}
\tilde{A}(z, \bar{z}) &= \left( \frac{1}{0} \right) + \int_{D} \frac{B(w)\beta(w, \bar{w})e^{2\theta(w,x,t)}}{w - z} \frac{d^2w}{\pi} \\
\tilde{B}(z, \bar{z}) &= \left( \frac{0}{1} \right) - \int_{\omega} \frac{\tilde{A}(w)\beta^*(w, \bar{w})e^{-2\theta(w,x,t)}}{w - z} \frac{d^2w}{\pi}.
\end{align*}
\]
(9)

For a given domain \( D \) and smooth function \( \beta(z, \bar{z}) \), the solution of the system \( 9 \) and the formula \( 8 \) provides the solution of the FNLs equation corresponding to our soliton gas. In the case \( \beta(z, \bar{z}) = n\pi^{n-1}r(z) \), with \( r(z) \) analytic in \( D \), we can apply Green’s theorem so that the area integral in \( 9 \) becomes a contour integral over the boundary \( \partial D \), namely
\[
\begin{align*}
\tilde{A}(z, \bar{z}) &= \left( \frac{1}{0} \right) + \int_{\partial D} \frac{\tilde{B}(w)r(w)w^m e^{2\theta(w,x,t)}}{w - z} \frac{dw}{\pi} \\
\tilde{B}(z, \bar{z}) &= \left( \frac{0}{1} \right) - \int_{\partial D} \frac{\tilde{A}(w)r^*(w)w^m e^{-2\theta(w,x,t)}}{w - z} \frac{dw}{\pi}.
\end{align*}
\]
(10)

For sufficiently smooth simply connected domains \( D \) the boundary \( \partial D \) can be described by the so-called Schwarz function \( S(z) \) of the domain \( D \) through the equation
\[
\frac{\tilde{A}(z, \bar{z})}{\tilde{B}(z, \bar{z})} = S(z).
\]

The Schwarz function admits analytic extension to a maximal domain \( D^0 \subset D \). For example, for quadrature domains, \( D^0 \) is just \( D \) minus a finite collection of points \( \Omega \). The simplest such quadrature domain is the disk, which is one of our examples below. For certain other domains we have that \( D \setminus D^0 \) may consist of a mother-body, i.e., a collection of smooth arcs. An example of this is the ellipse, which will be our second example.

**Deterministic soliton gas on quadrature domains.**

We start by considering the class of domains
\[
D := \left\{ z \in \mathbb{C} \text{ s.t. } |(z - c_0)^m - c_1| < \rho \right\}, \quad m \in \mathbb{N},
\]
(11)
with \( c_0 \in \mathbb{C}^+ \) and \( |c_1|, \rho > 0 \) sufficiently small so that \( D \subset \mathbb{C}^+ \). When \( m = 1 \) such domain coincides with the disk \( \mathbb{D} \) of radius \( \rho > 0 \) centred at \( z_0 = c_0 + c_1 \). When \( m > 1 \) the domain \( D \) has a \( m \)-fold symmetry about \( c_0 \) and is simply connected if \( |c_1| \leq \rho \), and otherwise it has \( m \) connected components \( \Omega \). The boundary of \( D \) is described by
\[
\tau = S(z), \quad S(z) = \left( c_1 + \frac{\rho^2}{(z - c_0)^m - c_1} \right)^{1/m}.
\]
(12)

The \( n \)-soliton solution. This solution is obtained from \( 10 \) by choosing \( m = n \) in \( 12 \). We then substitute \( \omega = S(w) \) in the contour integral \( 10 \) and use the residue theorem at the \( n \) poles given by the solution of the equation \( (z - c_0)^n = c_1 \). The corresponding solution to the FNLs equation coincides with a \( n \)-soliton solution. To simplify the analysis we flesh out the case \( n = 1 \) with \( D = \mathbb{D} \) the disc centred at \( z_0 = c_0 + c_1 \) of radius \( \rho \). In this case, in equation \( 10 \), we can substitute \( \omega \) by Schwarz function of the disk \( 12 \), and then use the residue theorem to obtain
\[
\begin{align*}
\tilde{A}(z, \bar{z}) &= \left( \frac{1}{0} \right) - \rho^2 \tilde{B}(z_0)r(z_0)e^{2\theta(z_0,x,t)} \\
\tilde{B}(z, \bar{z}) &= \left( \frac{0}{1} \right) + \rho^2 \tilde{A}(z_0)r(z_0)e^{-2\theta(z_0,x,t)}.
\end{align*}
\]
(13)

for \( z \notin D \cup \Omega \) with
\[
\begin{align*}
\tilde{A}(z_0) &= \left( \frac{1}{0} \right) - \rho^2 \tilde{B}(z_0)r(z_0)e^{2\theta(z_0,x,t)} \\
\tilde{B}(z_0) &= \left( \frac{0}{1} \right) + \rho^2 \tilde{A}(z_0)r(z_0)e^{-2\theta(z_0,x,t)}.
\end{align*}
\]
(14)

Plugging the solution of \( 14 \) in \( 13 \) we derive the first component of \( \tilde{B}(z, \bar{z}) \) in the region \( z \notin D \cup \Omega \), namely
\[
\tilde{B}(z, \bar{z}) \left|_{w = z_0} \right. = -\rho^2 r(z_0)e^{-2\theta(z_0,x,t)} \frac{z - z_0}{(z_0 - \bar{z}_0)^2 - \rho^2 |r(z_0)|^2 e^{2\theta(z_0,x,t)} - 2\theta(z_0,x,t)}.
\]

From the above expression we obtain from \( 8 \) the one soliton solution \( 2 \) of the FNLs \( 1 \) equation with \( z_0 = a + ib \), with peak position \( x_0 \) and phase shift \( \phi \) given by
\[
x_0 := \log(\rho^2 |r(z_0)|^2) - \log(2b), \quad \phi_0 := \text{arg}(r(z_0)).
\]
(15)

We observe that the radius \( \rho \) of the disk and the value of the function \( r(z) \) at \( z_0 \) contribute to the phase shift of the soliton but not to its amplitude or velocity, which are uniquely determined by the center of the disk \( z_0 \).

**Soluton solution of order \( n \).** We now consider the case \( \beta(z) = z^{n-1}r(z) \), where \( r(z) \) is analytic in \( D \). Using again the residue theorem, we reduce \( 10 \) to another algebraic problem:
\[
\begin{align*}
\tilde{A}(z, \bar{z}) &= \left( \frac{1}{0} \right) + \sum_{j=0}^{n-1} \frac{\gamma_j^n}{n(n - j - 1)!} \left( \frac{n}{j} \right) \times \\
&\quad \times \frac{d^{n-j-1} B(w)r(w)e^{2\theta(w,x,t)}}{dw^{n-j-1}} \bigg|_{w = z_0} \\
\tilde{B}(z, \bar{z}) &= \left( \frac{0}{1} \right) - \sum_{j=0}^{n-1} \frac{\alpha_j^n}{n(n - j - 1)!} \left( \frac{n}{j} \right) \times \\
&\quad \times \frac{d^{n-j-1} \tilde{B}(w)r(w)e^{-2\theta(w,x,t)}}{dw^{n-j-1}} \bigg|_{w = z_0},
\end{align*}
\]
(16)
for $z \notin \overline{D} \cup \overline{D}$, where $\gamma_n^s := \rho^{2(n-j)} z_0^j$ and $\alpha_n^s := \rho^{2(n-j)} z_0^j$.

If we evaluate the derivatives in (10) we obtain a linear system of $4n$ equation in $4n$ variables $\vec{A}(z_0), \vec{A}'(z_0), \vec{B}(z_0), \vec{B}'(z_0), \vec{B}^n(z_0)$. By solving it and then applying the equation (9), one derives the one-soliton solution of order $n$.

Elliptic Domain. We now consider the case in which $D$ coincide with an elliptic domain $E$. For the sake of simplicity, we assume that the focal points $i\alpha_1$ and $i\alpha_2$ of the ellipse lie on the imaginary axis and $\alpha_2 > \alpha_1 > 0$. The equation of the ellipse is $\sqrt{x^2 + (y - \alpha_1)^2} + \sqrt{x^2 + (y - \alpha_2)^2} = 2\rho > 0$, where $\rho$ is chosen sufficiently small so that $E$ lies in the upper half space. We choose $\beta(z) = r(z)$ to be analytic in $E$. In this case in equations (10) $n = 1$ and one has to consider the Schwarz function of the ellipse, namely $\bar{z} = S(z) :$

$$S(z) = 2\frac{\rho^2}{c^2}(z - iy_0) - z + 2\frac{\rho}{c}\sqrt{\rho^2 - c^2} R(z)$$

where $R(z) := \sqrt{(z - i\alpha_1)(z - i\alpha_2)}$, $y_0 = \frac{\alpha_1 + \alpha_2}{2}$ and $c = \frac{\alpha_2 - \alpha_1}{2}$. The function $S(z)$ is analytic in $\mathbb{C}$ away from the segment $I := [i\alpha_1, i\alpha_2]$, with boundary values $S_{\pm}(z)$. The integral along the boundary $\partial E$ of the ellipse in (10) can be deformed to a line integral on the segment $I (\bar{I} := [-i\alpha_2, -i\alpha_1])$. The corresponding integral equation is equivalent to the Riemann-Hilbert problem for the matrix function $\Gamma(z) = [\vec{A}(z); \vec{B}(z)]$, analytic in $\mathbb{C} \setminus (I \cup \bar{I})$ with jump conditions

$$\Gamma_+(z) = \Gamma_-(z)e^{\theta(z;x,t)\sigma_3}G(z)e^{-\theta(z;x,t)\sigma_3}$$

$$G(z) = \begin{pmatrix} 1 & \chi D z \delta S(z) \beta(z) \\ -\frac{1}{\chi D} S(z) \beta^*(z) & 1 \end{pmatrix}$$

where $\delta S(z) = S_+(z) - S_-(z)$, and $\Gamma(z) = \mathbb{I} + O(\frac{1}{z})$, as $z \to \infty$. We can find the same RHP (18) also when we study the problem (4) with an infinite number of spectral points uniformly distributed along the segments $I \cup \bar{I}$.

For $t = 0$, the initial datum $\psi_0(x)$ associated to the solution of the RHP (18) turns out to be step-like oscillatory. Indeed from the steepest descent method following the lines (13) as $x \to -\infty$ we derive the elliptic function

$$\psi_0(x) = -i \frac{\theta(0) \theta(\frac{\Omega x - i\Delta}{2\pi} - \frac{1}{2})}{\theta(\frac{\Omega x - i\Delta}{2\pi}) \theta(\frac{\Omega x + i\Delta}{2\pi})} (\alpha_2 + \alpha_1) + O(x^{-1})$$

where $\theta(z) = \sum_{n \in \mathbb{Z}} e^{\pi i n \sigma_3 + \pi i n \tau}$ is the Jacobi theta function of modulus $\tau = iK(m')/2K(m)$, $K(m) = \int_0^{\pi/2} d\theta/\sqrt{1 - m^2 \sin^2 \theta}$ with $m = \frac{\alpha_1}{\alpha_2}$ and $m' = \sqrt{1 - m^2}$.

The wave number $\Omega := \pi \alpha_2/K(m)$ and $\Delta$ is a constant which depends on $\delta S(z)\beta(z)$. For $x \to +\infty$ the initial datum goes to zero exponentially fast: $\psi_0(x) = e^{-\alpha_2 x}$, for some constant $c_0 > 0$. When $\alpha_1 > \alpha_2$ the ellipse degenerates to the circle and one recovers the one soliton solution.

Conclusions. We have considered a gas of $N$ solitons of the FNLS equation in the limit $N \to \infty$. The soliton spectrum and norming constants $(z_j, c_j)_{j=1}^{N-1}$ are chosen in such a way that the discrete spectral measure $N^{-1} \sum c_j \delta z_j$ converges to the measure $d\mu = \beta(z, \Omega)\chi_D(z)dz$ for a smooth function $\beta(z, \Omega)$ with $\chi_D$ the characteristic function of a domain $D \subset \mathbb{C}^+$. We then showed that when the domain $D$ is a disc and the soliton density $\beta(z, \Omega)$ is an analytic function, then the corresponding deterministic soliton gas initial datum coincides with the one-soliton solution with point spectrum the center of the circle. We call this surprising effect soliton shielding because the interaction of infinite solitons with point spectrum converging to an analytic measure in the disc reduces out to a one-soliton solution. For other choices of the domain $D$ or the density $\beta(z, \Omega)$ we obtained a $n$-soliton solution or a one-soliton solution of order $n$. When the domain $D$ is an ellipse, we showed that the spectral measure is equivalent to solitons concentrating on lines connecting the foci of the ellipse and the soliton gas initial datum is asymptotically step-like oscillatory.
