Local normal approximations and probability metric bounds for the matrix-variate $T$ distribution and its application to Hotelling’s $T$ statistic

Frédéric Ouimet\textsuperscript{a,1,*}

\textsuperscript{a}McGill University, Montreal, QC H3A 0B9, Canada.

Abstract

In this paper, we develop local expansions for the ratio of the centered matrix-variate $T$ density to the centered matrix-variate normal density with the same covariances. The approximations are used to derive upper bounds on several probability metrics (such as the total variation and Hellinger distance) between the corresponding induced measures.

Keywords: asymptotic statistics, expansion, local approximation, matrix-variate normal distribution, normal approximation, matrix-variate $T$ distribution, $T$ distribution, Student distribution, Hotelling’s $T$-squared distribution, Hotelling’s $T$ statistic, total variation

1. Introduction

For any $n \in \mathbb{N}$, define the space of (real symmetric) positive definite matrices of size $n \times n$ as follows:

$$S^n_{++} := \{ M \in \mathbb{R}^{n \times n} : M \text{ is symmetric and positive definite} \}.$$  

For $d, m \in \mathbb{N}$, $\nu > 0$, $M \in \mathbb{R}^{d \times m}$, $\Sigma \in S^d_{++}$ and $\Omega \in S^m_{++}$, the density function of the centered (and normalized) matrix-variate $T$ distribution, hereafter denoted by $T_{d,m}(\nu, \Sigma, \Omega)$, is defined, for all $X \in \mathbb{R}^{d \times m}$, by

$$K_{\nu, \Sigma, \Omega}(X) := \frac{\nu^{\frac{d}{2}(\nu + m + d - 1)}}{(d \pi)^{md/2}|\Sigma|^{m/2}|\Omega|^{d/2}} \int \frac{|I_d + \nu^{-1} \Sigma^{-1} X \Omega^{-1} X^T|^{-(\nu + m + d - 1)/2}}{(\nu \pi)^{(d-1)/2}} ds,$$  

(see, e.g., (Gupta & Nagar, 1999, Definition 4.2.1)) where $\nu$ is the number of degrees of freedom, and

$$\Gamma_d(z) = \int_{S^d_{++}} |S|^{-(d+1)/2} \exp(-\text{tr}(S)) dS = \pi^{d(d-1)/4} \prod_{j=1}^{d} \Gamma \left( z - \frac{j - 1}{2} \right), \quad \Re(z) > \frac{d - 1}{2},$$

denotes the multivariate gamma function, see, e.g., (Olver et al., 2010, Section 35.3) and Nagar et al. (2013), and

$$\Gamma(z) = \int_{0}^{\infty} t^{z-1} e^{-t} dt, \quad \Re(z) > 0,$$

is the classical gamma function. The mean and covariance matrix for the vectorization of $T \sim T_{d,m}(\nu, \Sigma, \Omega)$, namely

$$\text{vec}(T) := (T_{11}, T_{21}, \ldots, T_{d1}, T_{12}, T_{22}, \ldots, T_{d2}, \ldots, T_{1m}, T_{2m}, \ldots, T_{dm})^T,$$

\((\text{vec}(\cdot))\) is the operator that stacks the columns of a matrix on top of each other) are known to be (see, e.g., Theorem 4.3.1 in Gupta & Nagar (1999), but be careful of the normalization):

\[
\mathbb{E}[\text{vec}(T)] = 0_{d m} \quad (\text{i.e., } \mathbb{E}[T] = 0_{d \times m}), \quad \text{and} \quad \text{Var}(\text{vec}(T^T)) = \frac{\nu}{(\nu - 2)} \Sigma \otimes \Omega, \quad \nu > 2.
\]

The first goal of our paper (Theorem 1) is to establish an asymptotic expansion for the ratio of the centered matrix-variate \(T\) density \((1.1)\) to the centered matrix-variate normal (MN) density with the same covariances. According to Gupta & Nagar (1999, Theorem 2.2.1), the ratio of the centered matrix-variate \(T\) density to the centered matrix-variate normal (MN) density (1.1) to the centered matrix-variate normal (MN) density with the same covariances. According to Gupta & Nagar (1999, Theorem 2.2.1), the density of the \(\text{MN}_{d,m}(0_{d \times m}, \Sigma \otimes \Omega)\) distribution is

\[
g_{\Sigma, \Omega}(X) = \exp \left( -\frac{1}{2} \text{tr} \left( \Sigma^{-1} X \Omega^{-1} X^\top \right) \right), \quad X \in \mathbb{R}^{d \times m}. \tag{1.2}
\]

The second goal of our paper (Theorem 2) is to apply the log-ratio expansion from Theorem 1 to derive upper bounds on multiple probability metrics between the measures induced by the centered matrix-variate \(T\) distribution and the corresponding centered matrix-variate normal distribution. In the special case \(m = 1\), this gives us probability metric upper bounds between the measure induced by Hotelling’s \(T\) statistic and the associated matrix-normal measure.

Here is a brief outline of the paper. Our main results are stated in Section 2 and proved in Section 3. Technical moment calculations are gathered in Section 4.

**Notation.** Throughout the paper, \(a = \mathcal{O}(b)\) means that \(\lim\sup |a/b| < C\) as \(\nu \to \infty\), where \(C > 0\) is a universal constant. Whenever \(C\) might depend on some parameter, we add a subscript (for example, \(a = \mathcal{O}_d(b)\)). The notation \(\text{tr}(\cdot)\) will denote the trace operator for matrices and \(|\cdot|\) their determinant. For a matrix \(\mathbb{M} \in \mathbb{R}^{d \times d}\) that is diagonalizable, \(\lambda_1(\mathbb{M}) \leq \cdots \leq \lambda_d(\mathbb{M})\) will denote its eigenvalues, and we let \(\lambda(\mathbb{M}) := (\lambda_1(\mathbb{M}), \ldots, \lambda_d(\mathbb{M}))^\top\).

2. **Main results**

In Theorem 1 below, we prove an asymptotic expansion for the ratio of the centered matrix-variate \(T\) density to the centered matrix-variate normal (MN) density with the same covariances. The case \(d = m = 1\) was proven recently in Ouimet (2022). The result extends significantly the convergence in distribution result from Theorem 4.3.4 in Gupta & Nagar (1999).

**Theorem 1.** Let \(d, m \in \mathbb{N}, \Sigma \in \mathcal{S}_{++}^d\) and \(\Omega \in \mathcal{S}_{++}^m\) be given. Pick any \(\eta \in (0,1)\) and let

\[
\mathcal{B}_{\nu, \Sigma, \Omega}(\eta) := \left\{ X \in \mathbb{R}^{d \times m} : \max_{1 \leq j \leq d} \frac{\delta_{\lambda_j}}{\sqrt{\nu - 2}} \leq \eta \nu^{-1/4} \right\}
\]

denote the bulk of the centered matrix-variate \(T\) distribution, where

\[
\Delta_X := \Sigma^{1/2} X \Omega^{-1/2} \quad \text{and} \quad \delta_{\lambda_j} := \sqrt{\frac{\nu - 2}{\nu}} \lambda_j(\Delta_X \Delta_X^\top), \quad 1 \leq j \leq d.
\]

Then, as \(\nu \to \infty\) and uniformly for \(X \in \mathcal{B}_{\nu, \Sigma, \Omega}(\eta)\), we have

\[
\log \left( \frac{[\nu/(\nu - 2)]^{md/2} K_{\nu, \Sigma, \Omega}(X)}{g_{\Sigma, \Omega}(X/\sqrt{\nu/(\nu - 2)})} \right) = \nu^{-1} \left\{ \frac{1}{4} \text{tr} \left( (\Delta_X \Delta_X^\top)^2 \right) - \frac{(m + d + 1)}{2d} \text{tr} \left( \Delta_X \Delta_X^\top \right) \right\} + \mathcal{O}_{d,m,\eta} \left( \frac{1 + \text{tr} \left( (\Delta_X \Delta_X^\top)^5 \right)}{\nu^4} \right). \tag{2.1}
\]
Below, we provide numerical evidence (displayed graphically) for the validity of the expansion in Theorem 1 when \(d = m = 2\). We compare three levels of approximation for various choices of \(S\). For any given \(S \in \mathcal{S}^d_{++}\), define

\[
E_0 := \sup_{X \in \mathcal{B}_{\nu, \Sigma, \Omega}(\nu^{-1/4})} \left| \log \left( \frac{[\nu/(\nu - 2)]^{md/2} K_{\nu, \Sigma, \Omega}(X)}{g_{\Sigma, \Omega}(X/\sqrt{\nu/(\nu - 2)})} \right) \right|, \tag{2.2}
\]

\[
E_1 := \sup_{X \in \mathcal{B}_{\nu, \Sigma, \Omega}(\nu^{-1/4})} \left| \log \left( \frac{[\nu/(\nu - 2)]^{md/2} K_{\nu, \Sigma, \Omega}(X)}{g_{\Sigma, \Omega}(X/\sqrt{\nu/(\nu - 2)})} \right) \right| - \nu^{-1} \left\{ \frac{1}{4} \text{tr} \left( (\Delta_X \Delta_X^\top)^2 \right) - \frac{(m + d + 1)}{2} \text{tr} \left( \Delta_X \Delta_X^\top \right) + \frac{md(m + d + 1)}{4} \right\},
\]

\[
E_2 := \sup_{X \in \mathcal{B}_{\nu, \Sigma, \Omega}(\nu^{-1/4})} \left| \log \left( \frac{[\nu/(\nu - 2)]^{md/2} K_{\nu, \Sigma, \Omega}(X)}{g_{\Sigma, \Omega}(X/\sqrt{\nu/(\nu - 2)})} \right) \right| - \nu^{-1} \left\{ \frac{1}{4} \text{tr} \left( (\Delta_X \Delta_X^\top)^2 \right) - \frac{(m + d + 1)}{2} \text{tr} \left( \Delta_X \Delta_X^\top \right) + \frac{md(m + d + 1)}{4} \right\} - \nu^{-2} \left\{ \frac{-1}{6} \text{tr} \left( (\Delta_X \Delta_X^\top)^3 \right) + \frac{(m + d - 1)}{4} \text{tr} \left( (\Delta_X \Delta_X^\top)^2 \right) - \frac{md}{2\nu} (13 + 2d^2 + 3d(-3 + m) - 9m + 2m^2) \right\}.
\]

In \(\mathbb{R}\), we use Equation (3.2) to evaluate the log-ratios inside \(E_0\), \(E_1\) and \(E_2\).

Note that \(X \in \mathcal{B}_{\nu, \Sigma, \Omega}(\nu^{-1/4})\) implies \(|\text{tr}(\Delta_X \Delta_X^\top)| \leq d\) for all \(k \in \mathbb{N}\), so we expect from Theorem 1 that the maximum errors above \((E_0, E_1\text{ and } E_2)\) will have the asymptotic behavior

\[
E_i = O_d(\nu^{-(1+i)}), \quad \text{for all } i \in \{0, 1, 2\},
\]

or equivalently,

\[
\lim_{\nu \to \infty} \frac{\log E_i}{\log(\nu^{-1})} \geq 1 + i, \quad \text{for all } i \in \{0, 1, 2\}. \tag{2.3}
\]

The property (2.3) is verified in Fig. 2.2 below, \(\Omega = I_2\) and various choices of \(\Sigma_{2 \times 2}\). Similarly, the corresponding the log-log plots of the errors as a function of \(\nu\) are displayed in Fig. 2.1. The simulations are limited to the range \(5 \leq \nu \leq 205\). The \(\mathbb{R}\) code that generated Figs. 2.1 and 2.2 can be found online at https://www.dropbox.com/s/qjp8cpiuuuhoue/simulations_LLT_matrix_T.R?dl=0.

As a consequence of the previous theorem, we can derive asymptotic upper bounds on the several probability metrics between the probability measures induced by the centered matrix-variate \(T\) distribution (1.1) and the corresponding centered matrix-variate normal distribution (1.2). The distance between Hotelling’s \(T\) statistic (Hotelling, 1931) and the corresponding matrix-variate normal distribution corresponds to the special case \(m = 1\).

**Theorem 2** (Probability metric upper bounds). Let \(d, m \in \mathbb{N}\), \(\Sigma \in \mathcal{S}^d_{++}\) and \(\Omega \in \mathcal{S}^m_{++}\) be given. Assume that \(X \sim T_{d,m}(\nu, \Sigma, \Omega)\), \(Y \sim MN_{d,m}(0_{d \times m}, \Sigma \otimes \Omega)\), and let \(\mathbb{P}_{\nu, \Sigma, \Omega}\) and \(\mathbb{Q}_{\Sigma, \Omega}\) be the laws of \(X\) and \(Y\), respectively. Then, as \(\nu \to \infty\),

\[
\text{dist}(\mathbb{P}_{\nu, \Sigma, \Omega}, \mathbb{Q}_{\Sigma, \Omega}) \leq \frac{C m^{3/2} d^{3/2}}{\nu} \quad \text{and} \quad \mathcal{H}(\mathbb{P}_{\nu, \Sigma, \Omega}, \mathbb{Q}_{\Sigma, \Omega}) \leq \sqrt{\frac{2C m^{3/2} d^{3/2}}{\nu},}
\]

where \(C > 0\) is a universal constant, \(\mathcal{H}(\cdot, \cdot)\) denotes the Hellinger distance, and \(\text{dist}(\cdot, \cdot)\) can be replaced by any of the following probability metrics: Total variation, Kolmogorov (or Uniform) metric, Lévy metric, Discrepancy metric, Prokhorov metric.
Fig. 2.1: Plots of \(1/E_1\) as a function of \(\nu\), for various choices of \(\Sigma\). Both the horizontal and vertical axes are on a logarithmic scale. The plots clearly illustrate how the addition of correction terms from Theorem 1 to the base approximation (2.2) improves it.

Fig. 2.2: Plots of \(\log(E_1)/\log(\nu^{-1})\) as a function of \(\nu\), for various choices of \(\Sigma\). The plots confirm (2.3) for our choices of \(\Sigma\) and bring strong evidence for the validity of Theorem 1.
3. Proofs

Proof of Theorem 1. First, we take the expression in (1.1) over the one in (1.2):

\[
\frac{[\nu/(\nu - 2)]^{md/2} K_{\nu, \Sigma, \Omega}(X)}{g_{\Sigma, \Omega}(X/\sqrt{\nu/(\nu - 2)})} = \left[ \frac{2}{\nu - 2} \right]^{md/2} \prod_{j=1}^{d} \frac{\Gamma(\frac{1}{2}(\nu + m + d - j))}{\Gamma(\frac{1}{2}(\nu + d - j))} \\
\cdot \exp \left( \frac{\nu - 2}{2\nu} \text{tr} \left( \Delta_X \Delta_X^\top \right) \right) \left| I_d + \nu^{-1} \Delta_X \Delta_X^\top \right|^{-(\nu + m + d - 1)/2}. \tag{3.1}
\]

The last determinant was obtained using the fact that the eigenvalues of a product of rectangular matrices are invariant under cyclic permutations (as long as the products remain well-defined).

Indeed, for all \( j \in \{1, 2, \ldots, d\} \), we have

\[
\lambda_j(I_d + \nu^{-1} \Sigma^{-1} X \Omega^{-1} X^\top) = 1 + \nu^{-1} \lambda_j(\Sigma^{-1} X \Omega^{-1} X^\top) = 1 + \nu^{-1} \lambda_j(\Delta_X \Delta_X^\top) = \lambda_j(I_d + \nu^{-1} \Delta_X \Delta_X^\top).
\]

By taking the logarithm on both sides of (3.1), we get

\[
\log \left( \frac{[\nu/(\nu - 2)]^{md/2} K_{\nu, \Sigma, \Omega}(X)}{g_{\Sigma, \Omega}(X/\sqrt{\nu/(\nu - 2)})} \right) = -\frac{md}{2} \log \left( \frac{\nu - 2}{2} \right) + \sum_{j=1}^{d} \left[ \log \Gamma\left( \frac{1}{2}(\nu + m + d - j) \right) - \log \Gamma\left( \frac{1}{2}(\nu + d - j) \right) \right] \tag{3.2}
\]

\[
+ \frac{1}{2} \sum_{j=1}^{d} \delta_{\lambda_j}^2 \frac{\nu + m + d - 1}{2} \sum_{j=1}^{d} \log \left( 1 + \left( \frac{\delta_{\lambda_j}}{\sqrt{\nu - 2}} \right)^2 \right).
\]

By applying the Taylor expansions,

\[
\log \Gamma\left( \frac{1}{2}(\nu + m + d - j) \right) - \log \Gamma\left( \frac{1}{2}(\nu + d - j) \right)
= \frac{1}{2}(\nu + m + d - j - 1) \log \left( \frac{1}{2}(\nu + m + d - j) \right) - \frac{1}{2}(\nu + d - j - 1) \log \left( \frac{1}{2}(\nu + d - j) \right)
- \frac{m}{2} \frac{2}{12(\nu + m + d - j)} - \frac{2}{12(\nu + d - j)}
- \frac{m}{2} \frac{2^3}{360(\nu + m + d - j)^3} + \frac{2^3}{360(\nu + d - j)^3} + O_{m,d}(\nu^{-4})
= \frac{m}{2} \log \left( \frac{\nu}{2} \right) + \frac{m}{4\nu} \left( -2d + 2j + m \right) - \frac{m}{12\nu^2} \left( 2 + 3d^2 + 3j^2 - 3j(-2 + m) - 3m + m^2 + d(-6 - 6j + 3m) \right)
+ \frac{m}{24\nu^3} \left( -4j(2 - 3m + m^2) + 4d(2 + 3j^2 - 3j(-2 + m) - 3m + m^2) \right) + O_{m,d}(\nu^{-4}).
\]

(see, e.g., (Abramowitz & Stegun, 1964, p.257)) and

\[
-\frac{md}{2} \log \left( \frac{\nu - 2}{2} \right) + \frac{md}{2} \log \left( \frac{\nu}{2} \right) = \frac{4md}{4\nu} + \frac{12md}{12\nu^2} + \frac{32md}{24\nu^3} + O_{m,d}(\nu^{-4}),
\]

and

\[
\log(1 + y) = y - \frac{1}{2} y^2 + \frac{1}{3} y^3 - \frac{1}{4} y^4 + O(y^5), \quad |y| < \eta < 1,
\]

in the above equation, we obtain

\[
\log \left( \frac{[\nu/(\nu - 2)]^{md/2} K_{\nu, \Sigma, \Omega}(X)}{g_{\Sigma, \Omega}(X/\sqrt{\nu/(\nu - 2)})} \right)
\]
\[
\begin{align*}
&= \sum_{j=1}^{d} \frac{m(2 + 2d - 2j + m)}{4\nu} - \sum_{j=1}^{d} \frac{m}{12\nu^2} \left\{ -10 + 3d^2 + 3j^2 - 3j(-2 + m) \right\} \\
&\quad + \sum_{j=1}^{d} \frac{m}{24\nu^3} \left\{ 32 + 4d^3 - 4j^3 - 6d^2(2 + 2j - m) + 6j^2(-2 + m) + (-2 + m)^2m \right\} \\
&\quad + \frac{1}{2} \sum_{j=1}^{d} \frac{\delta_{\lambda_j}^2}{\nu} - \frac{(\nu + m + d - 1)}{2} \sum_{j=1}^{d} \left( \frac{\delta_{\lambda_j}}{\sqrt{\nu - 2}} \right)^2 \\
&\quad + \frac{(\nu + m + d - 1)}{4} \sum_{j=1}^{d} \left( \frac{\delta_{\lambda_j}}{\sqrt{\nu - 2}} \right)^4 - \frac{(\nu + m + d - 1)}{6} \sum_{j=1}^{d} \left( \frac{\delta_{\lambda_j}}{\sqrt{\nu - 2}} \right)^6 \\
&\quad + \frac{(\nu + m + d - 1)}{8} \sum_{j=1}^{d} \left( \frac{\delta_{\lambda_j}}{\sqrt{\nu - 2}} \right)^8 + O_{d,m,\eta} \left( \frac{1 + \max_{1 \leq j \leq d} |\delta_{\lambda_j}|^{10}}{\nu^4} \right),
\end{align*}
\]

Now,
\[
\begin{align*}
1 & - \frac{\nu + m + d - 1}{2(\nu - 2)} = - \frac{(m + d + 1)}{2\nu} - \frac{(m + d + 1)}{\nu^2} - \frac{2(m + d + 1)}{\nu^3} + O_{m,d}(\nu^{-4}), \\
\frac{\nu + m + d - 1}{4(\nu - 2)^2} &= \frac{1}{4\nu} + \frac{(m + d + 3)}{4\nu^2} + \frac{(m + d + 2)}{\nu^3} + O_{m,d}(\nu^{-4}), \\
\frac{\nu + m + d - 1}{6(\nu - 2)^3} &= \frac{1}{6\nu^2} - \frac{(m + d + 5)}{6\nu^3} + O_{m,d}(\nu^{-4}), \\
\frac{\nu + m + d - 1}{8(\nu - 2)^4} &= \frac{1}{8\nu^3} + O_{m,d}(\nu^{-4}),
\end{align*}
\]

so we can rewrite (3.3) as
\[
\log \left( \frac{[\nu/(\nu - 2)]^{md/2} K_{\nu,\Sigma,\Omega}(X)}{g_{\nu,\Sigma,\Omega}(X/\sqrt{\nu/(\nu - 2)})} \right)
\]
\[
= \nu^{-1} \sum_{j=1}^{d} \left\{ \frac{1}{4} \delta_{\lambda_j}^4 - \frac{(m + d + 1)}{2} \delta_{\lambda_j}^2 + \frac{m(2 + 2d - 2j + m)}{4} \right\} \\
+ \nu^{-2} \sum_{j=1}^{d} \left\{ -\frac{1}{6} \delta_{\lambda_j}^6 + \frac{(m + d + 3)}{4} \delta_{\lambda_j}^4 - \frac{(m + d + 1)}{2} \delta_{\lambda_j}^2 \right\} \\
+ \nu^{-3} \sum_{j=1}^{d} \left\{ \frac{1}{8} \delta_{\lambda_j}^8 - \frac{(m + d + 5)}{6} \delta_{\lambda_j}^6 + \frac{(m + d + 2)}{4} \delta_{\lambda_j}^4 - \frac{2(m + d + 1)}{2} \delta_{\lambda_j}^2 \right\} \\
+ O_{d,m,\eta} \left( \frac{1 + \max_{1 \leq j \leq d} |\delta_{\lambda_j}|^{10}}{\nu^4} \right),
\]

which proves (2.1) after some simplifications with Mathematica. \(\square\)

**Proof of Theorem 2.** By the comparison of the total variation norm \(\| \cdot \|\) with the Hellinger distance on page 726 of Carter (2002), we already know that
\[
\| P_{\nu, \Sigma, \Omega} - Q_{\Sigma, \Omega} \| \leq \sqrt{2 \mathbb{P} \left( X \in B_{\nu, \Sigma, \Omega}(1/2) \right) + \mathbb{E} \left[ \log \left( \frac{dP_{\nu, \Sigma, \Omega}}{dQ_{\Sigma, \Omega}} \right)(X) 1_{\{X \in B_{\nu, \Sigma, \Omega}(1/2)\}} \right]}. \quad (3.4)
\]
Given that $\Delta_X = \Sigma^{-1/2}X\Omega^{-1/2} \sim T_{d,m}(\nu, I_d, I_m)$ by Theorem 4.3.5 in Gupta & Nagar (1999), we know, by Theorem 4.2.1 in Gupta & Nagar (1999), that

$$\Delta_X \overset{\text{law}}{=} (\nu^{-1}S)^{-1/2}Z,$$

for $S \sim \text{Wishart}_{d \times d}(\nu + d - 1, I_d)$ and $Z \sim \text{MN}_{d \times m}(0_{d \times m}, I_d \otimes I_m)$ that are independent, so that, by Theorem 3.3.3 and Theorem 3.3.1 in Gupta & Nagar (1999), we have

$$\Delta_X \Delta_X^\top | S \sim \text{Wishart}_{d \times d}(m, \nu S^{-1}). \quad (3.5)$$

Therefore, by conditioning on $S$, then by applying the sub-multiplicativity of the largest eigenvalue for nonnegative definite matrices, a large deviation bound on the maximum eigenvalue of a Wishart matrix (which is sub-exponential), we get, for $\nu$ large enough,

$$\mathbb{P}(X \in B_{\nu, \Sigma, \Omega}(1/2)) \leq \mathbb{E}\left[\mathbb{P}\left(\lambda_d(\Delta_X \Delta_X^\top) > \frac{\nu^{1/2}}{4} \mid S\right)\right]$$

and

$$\leq \mathbb{E}\left[\mathbb{P}\left(\lambda_d((\nu^{-1}S)^{-1/2})\lambda_d(ZZ^\top)\lambda_d((\nu^{-1}S)^{-1/2}) > \frac{\nu^{1/2}}{4} \mid S\right)\right]$$

and

$$\leq \mathbb{E}\left[\exp\left(-\frac{\lambda_1(S)}{100md \nu^{1/2}}\right)\right] \leq \exp\left(-\frac{\nu^{1/2}}{10^4 md}\right). \quad (3.6)$$

By Theorem 1, we also have

$$\mathbb{E}\left[\log \left(\frac{d\mathbb{P}_{\nu, \Sigma, \Omega}}{d\mathbb{Q}_{\Sigma, \Omega}}(X)\right) \mathbb{1}_{\{X \in B_{\nu, \Sigma, \Omega}(1/2)\}}\right]$$

$\quad = \nu^{-1}\left\{ \frac{\frac{1}{2} \cdot (\nu - 2)^2}{2} \cdot \mathbb{E}\left[\text{tr}\left(\left((\Delta_X \Delta_X^\top)^2\right)^2\right)\right] + \frac{md(m + d + 1)}{4}\right\}$

$\quad + \nu^{-1}\left\{ \mathcal{O}\left(\mathbb{E}\left[\text{tr}\left((\Delta_X \Delta_X^\top)^2\right) \mathbb{1}_{\{X \in B_{\nu, \Sigma, \Omega}(1/2)\}}\right]\right) + \mathcal{O}(m(m + d))\right\}$

$\quad + \nu^{-2}\left\{ \mathcal{O}\left(\mathbb{E}\left[\text{tr}\left((\Delta_X \Delta_X^\top)^3\right)\right]\right) + \mathcal{O}(m)\right\}$

$\quad + \nu^{-2}\left\{ \mathcal{O}\left(\mathbb{E}\left[\text{tr}\left((\Delta_X \Delta_X^\top)^3\right)\right]\right)\right\}.$

On the right-hand side, the first line is estimated using Lemma 1, and the second line is bounded using Lemma 2. We find

$$\mathbb{E}\left[\log \left(\frac{d\mathbb{P}_{\nu, \Sigma, \Omega}}{d\mathbb{Q}_{\Sigma, \Omega}}(X)\right) \mathbb{1}_{\{X \in B_{\nu, \Sigma, \Omega}(1/2)\}}\right] = \mathcal{O}(m^3d^3\nu^{-2}).$$

Putting (3.6) and (3.7) together in (3.4) gives the conclusion.

4. Technical computations

Below, we compute the expectations for some traces of powers of the matrix-variate Student distribution. The lemma is used to estimate some trace moments and the $\asymp \nu^{-1}$ errors in (3.7) of the proof of Theorem 2, and also as a preliminary result for the proof of Lemma 2.
Lemma 1. Let \( d, m \in \mathbb{N}, \Sigma \in \mathcal{S}^d_{++}, \) and \( \Omega \in \mathcal{S}^m_{++} \) be given. If \( X \sim T_{d,m}(\nu, \Sigma, \Omega) \) according to (1.1), then
\[
\mathbb{E} \left[ \text{tr} \left( \Delta_X \Delta_X^\top \right) \right] = \frac{md\nu}{\nu - 2} \sim md, \tag{4.1}
\]
\[
\mathbb{E} \left[ \text{tr} \left( (\Delta_X \Delta_X^\top)^2 \right) \right] = \frac{md\nu^2 \{(m + d)(\nu - 2) + \nu + md\}}{(\nu - 1)(\nu - 2)(\nu - 4)} \sim md(m + d + 1), \tag{4.2}
\]
where recall \( \Delta_X := \Sigma^{-1/2}X\Omega^{-1/2} \).

Proof of Lemma 1. For \( W \sim \text{Wishart}_{d \times d}(n, \mathbb{V}) \) with \( n > 0 \) and \( \mathbb{V} \in \mathcal{S}^d_{++} \), we know from (Gupta & Nagar, 1999, p.99) (alternatively, see (de Waal & Nel, 1973, p.66) or (Letac & Massam, 2004, p.308)) that
\[
\mathbb{E}[W] = n \mathbb{V} \quad \text{and} \quad \mathbb{E}[W^2] = n \{(n + 1) \mathbb{V} + \text{tr}(\mathbb{V}) I_d\} \mathbb{V},
\]
and from (Gupta & Nagar, 1999, p.99–100) (alternatively, see Haff (1979) and (Letac & Massam, 2004, p.308), or (von Rosen, 1988, p.101-103)) that
\[
\mathbb{E}[W^{-1}] = \frac{\mathbb{V}}{n - d - 1}, \quad \text{for } n - d - 1 > 0,
\]
\[
\mathbb{E}[W^{-2}] = \frac{\text{tr}(\mathbb{V}^{-1}) W^{-1} + (n - d - 1) W^{-2}}{(n - d)(n - d - 1)(n - d - 3)}, \quad \text{for } n - d - 3 > 0,
\]
and from (von Rosen, 1988, Corollary 3.1) that
\[
\mathbb{E}[\text{tr}(W^{-1}) W^{-1}] = \frac{(n - d - 2) \text{tr}(\mathbb{V}^{-1}) W^{-1} + 2 W^{-2}}{(n - d)(n - d - 1)(n - d - 3)}, \quad \text{for } n - d - 3 > 0.
\]
Therefore, by combining the above moment estimates with (3.5), we have
\[
\mathbb{E} \left[ \Delta_X \Delta_X^\top \right] = \mathbb{E} \left[ \mathbb{E} \Delta_X \Delta_X^\top | \mathcal{S} \right] = \mathbb{E} [m (\nu \mathcal{S}^{-1})] = m \nu \mathbb{E} [\mathcal{S}^{-1}] = \frac{m \nu}{\nu - 2} I_d,
\]
\[
\mathbb{E} \left[ (\Delta_X \Delta_X^\top)^2 \right] = \mathbb{E} \left[ \mathbb{E} (\Delta_X \Delta_X^\top)^2 | \mathcal{S} \right] = \mathbb{E} \left[ m \left\{ (m + 1) (\nu \mathcal{S}^{-1}) + \text{tr}(\nu \mathcal{S}^{-1}) I_d \right\} (\nu \mathcal{S}^{-1}) \right]
= m \nu^2 \left\{ (m + 1) \mathbb{E} [\mathcal{S}^{-2}] + \mathbb{E} [\text{tr}(\mathcal{S}^{-1}) \mathcal{S}^{-1}] \right\}
= m \nu^2 \left\{ (m + 1) (\nu + d - 2) + (\nu - 3) d + 2 \right\}
\frac{(\nu - 1)(\nu - 2)(\nu - 4)}{I_d},
\]
By linearity, the trace of an expectation is the expectation of the trace, so (4.1) and (4.2) follow from the above equations.

We can also estimate the moments of Lemma 1 on various events. The lemma below is used to estimate the \( \approx \nu^{-1/2} \) errors in (3.7) of the proof of Theorem 2.

Lemma 2. Let \( d, m \in \mathbb{N}, \Sigma \in \mathcal{S}^d_{++}, \) and \( \Omega \in \mathcal{S}^m_{++} \) be given, and let \( A \in \mathcal{B} \mathcal{(R}^d \times m) \) be a Borel set. If \( X \sim T_{d,m}(\nu, \Sigma, \Omega) \) according to (1.1), then, for \( \nu \) large enough,
\[
\left| \mathbb{E} \left[ \text{tr}(\Delta_X \Delta_X^\top) \mathbb{1}_{\{X \in A\}} \right] \right| \leq 2 m^{1/2} d^{3/2} (\mathbb{P}(X \in A^c))^{1/2}, \tag{4.3}
\]
\[
\left| \mathbb{E} \left[ \text{tr} \left( (\Delta_X \Delta_X^\top)^2 \right) \mathbb{1}_{\{X \in A\}} \right] - \frac{md\nu^2 \{(m + d)(\nu - 2) + \nu + md\}}{(\nu - 1)(\nu - 2)(\nu - 4)} \right| \leq 100 m^2 d^{5/2} (\mathbb{P}(X \in A^c))^{1/4}, \tag{4.4}
\]
where recall \( \Delta_X := \Sigma^{-1/2}X\Omega^{-1/2} \).
**Proof of Lemma 2.** By Lemma 1, the Cauchy-Schwarz inequality, and Jensen’s inequality

\[
(\text{tr}(\Delta X \Delta_X^T))^2 \leq d \cdot (\text{tr}(\Delta X \Delta_X^T))^2,
\]

we have

\[
\left| \mathbb{E} \left[ \text{tr}(\Delta X \Delta_X^T) \mathbb{1}_{\{X \in A\}} \right] \right| = \left| \mathbb{E} \left[ \text{tr}(\Delta X \Delta_X^T) \mathbb{1}_{\{X \in A^c\}} \right] \right| \\
\leq \left( \mathbb{E} \left[ (\text{tr}(\Delta X \Delta_X^T))^2 \right] \right)^{1/2} \left( \mathbb{P} (X \in A^c) \right)^{1/2} \\
\leq \left( d \cdot \mathbb{E} \left[ (\text{tr}(\Delta X \Delta_X^T))^2 \right] \right)^{1/2} \left( \mathbb{P} (X \in A^c) \right)^{1/2} \\
\leq 2m^{1/2}d^{3/2} \left( \mathbb{P} (X \in A^c) \right)^{1/2},
\]

which proves (4.3). Similarly, by Lemma 1, Holder’s inequality, and Jensen’s inequality

\[
(\text{tr}(\Delta X \Delta_X^T))^2 \leq d \text{tr}(\Delta X \Delta_X^T)^4,
\]

we have, for \( \nu \) large enough,

\[
\left| \mathbb{E} \left[ (\text{tr}(\Delta X \Delta_X^T)^2) \mathbb{1}_{\{X \in A\}} \right] \right| - \frac{md\nu^2 \{(m+d)(\nu - 2) + \nu + md\}}{(\nu - 1)(\nu - 2)(\nu - 4)} \\
\leq \left| \mathbb{E} \left[ (\text{tr}(\Delta X \Delta_X^T)^2) \mathbb{1}_{\{X \in A^c\}} \right] \right| \\
\leq \left( \mathbb{E} \left[ (\text{tr}(\Delta X \Delta_X^T)^2))^2 \right] \right)^{1/2} \left( \mathbb{P} (X \in A^c) \right)^{1/4} \\
\leq \left( d \cdot \mathbb{E} \left[ (\text{tr}(\Delta X \Delta_X^T)^4) \right] \right)^{1/2} \left( \mathbb{P} (X \in A^c) \right)^{1/4} \\
\leq \left( d \cdot 10^4(m^2d^4) \right)^{1/2} \left( \mathbb{P} (X \in A^c) \right)^{1/4} \leq 100m^2d^{5/2} \left( \mathbb{P} (X \in A^c) \right)^{1/4},
\]

which proves (4.4). This ends the proof. \( \square \)
