Abstract
Statistical modeling and inference problems with sample sizes substantially smaller than the number of available covariates are challenging. Chakraborty et al. (2012) did a full hierarchical Bayesian analysis of nonlinear regression in such situations using relevance vector machines based on reproducing kernel Hilbert space (RKHS). But they did not provide any theoretical properties associated with their procedure. The present paper revisits their problem, introduces a new class of global-local priors different from theirs, and provides results on posterior consistency as well as posterior contraction rates.

Keywords: Global-local priors; Posterior Contraction; Reproducing kernel Hilbert space.

1. Introduction
Regression techniques are widely used virtually in any field demanding quantitative analysis. Even until today, much of this analysis relies on a linear relationship between the predictors and the response variables. This, however, is often more a convenience than reality. There is no dearth of problems of applied interest where the linearity assumption fails, and non-linear regression is called for. Fortunately, recent advancement in computer capability has allowed statisticians to tackle such non-linear regression problems. In addition, statisticians are now able to handle data where the number of covariates (say, $p$) far exceeds the sample size (say, $n$), a situation of natural occurrence, for example in microarray experiments, image analysis, and a variety of commonly encountered problems in medicine, business, economics, sociology and others.

Chakraborty et al. (2012) considered one such problem arising from near infrared (NIR) spectroscopy where spectral measurements typically produce many more covariates (wavelets, channels) than calibration measurements (samples). They considered a full hierarchical Bayesian analysis of such data using relevance vector machines (RVM’s). RVM’s are machine learning techniques, originally introduced by Tipping (2000, 2001) and Bishop and Tipping (2000). These authors essentially used an empirical Bayes procedure involving Type II maximum likelihood (Good, 1965) estimators of prior parameters. Unlike them, Chakraborty et al. (2012) used a hierarchical Bayesian procedure by assigning distributions to the prior parameters. Hierarchical Bayes procedures typically hold advantage over empirical Bayes
procedures in that unlike the latter, they can model the uncertainty in estimating the prior parameters, thus particularly useful for prediction.

The RVM regression approach of Chakraborty et al. (2012) was based on reproducing kernel Hilbert space (RKHS). While they could implement their procedure via Markov chain Monte Carlo (MCMC), they did not establish any theoretical properties of their method. The basic objective of this paper is to provide theoretical underpinnings to the problem introduced by Chakraborty et al. (2012). We have introduced instead a class of global-local priors different from the one of Chakraborty et al. (2012). Global-local priors are widely used in high-dimensional statistics, for example, by Carvalho et al. (2010), Polson and Scott (2010) and many others. One of the attractive features of our priors is that they can handle both sparse and dense situations, and the asymptotics is based on the sample size \( n \) tending to infinity.

Our paper essentially consist of two parts. In the first part of this paper, we have proved under minimal assumptions posterior consistency as well as posterior contraction rate for a bounded kernel which includes the well-used Gaussian kernel under some mild conditions. As mentioned, the results are very general where the number of covariates can far exceed the sample size \( n \). The prior used is a certain class of global-local priors, and the global parameter plays a key role in establishing posterior consistency as well as posterior contraction. With appropriate choice of this parameter, we are able to obtain asymptotic minimax posterior contraction rate as well. The second part of the paper deals with polynomial kernels where we are able to establish posterior consistency as well as posterior contraction rates.

The outline of the remaining sections is as follows. We have introduced the hierarchical Bayesian model in Section 2 for bounded kernels and have derived the marginal posterior of the regression parameter of interest. Section 3 deals with the bounded kernel and posterior consistency and contraction are established under the proposed model. Section 4 deals with results involving polynomial kernels with fixed kernel parameter. Some final discussions are made in Section 5.

2. Hierarchical Regression Model Based on RKHS

In this section we introduce the reproducing kernel Hilbert space (RKHS) and hierarchical Bayesian model based on RKHS.

2.1 Regression Model Base on RKHS

For a regression model, we have a training set \( \{Y_{in}, x_i\}, i = 1, 2, \cdots, n \), where \( Y_{in} \) is the response variable and \( x_i = (x_{i1}, \cdots, x_{ip})^T \) is the vector of covariates of size \( p \) corresponding to \( Y_{in} \). Given the training data our goal is to find an appropriate function \( f(x) \) to predict the response \( y \) in the test set based on the covariates \( x \). This can be viewed as a regularization problem of the form

\[
\min_{f \in \mathbb{F}} \left[ \sum_{i=1}^{n} L(Y_{in}, f(x_i)) + \lambda J(f) \right] \tag{1}
\]
where $L(y, f(x))$ is a loss function, $J(f)$ is a penalty functional, $\lambda > 0$ is the smoothing parameter, and $\mathbb{H}$ is a space of functions on which $J(f)$ is defined. In this article, we consider $\mathbb{H}$ to be a reproducing kernel Hilbert space (RKHS) with kernel $K$, and we denote it by $\mathbb{H}_K$. A formal definition of RKHS is given in Aronszajn (1950), Parzen (1970) and Wahba (1990).

For an $h \in \mathbb{H}_K$, if $f(x) = h(x)$, we take $J(f) = \| h \|_{\mathbb{H}_K}$ and rewrite (1) as

$$min_{h \in \mathbb{H}_K} [\sum_{i=1}^{n} L(Y_i, h(x_i)) + \lambda \| h \|_{\mathbb{H}_K}].$$

The estimate of $f$ is obtained as a solution of (2). It can be shown that the solution is finite-dimensional and leads to a representation of $f$ as

$$f(x_i) = \sum_{j=1}^{n} \beta_j K(x_i, x_j) \theta.$$ (3)

Two classical choices of the reproducing kernel $K$ are
(a) The Gaussian kernel $K(x_i, x_j) = exp(-||x_i - x_j||^2/\theta)$, $\theta > 0$,
(b) The polynomial kernel $K(x_i, x_j) = (x_i \cdot x_j + 1)\theta$, $\theta > 0$.

2.2 Hierarchical Bayes Relevance Vector Machine

Assume the true model is $Y_n = K_n \beta_0 + \epsilon_n$. Here $Y_n = (Y_1, \cdots, Y_n)^T$, $\epsilon_n \sim N(0, \sigma_0^2 I_n)$, $K_{nij} = K(x_i, x_j | \theta)$, $i, j = 1, 2, \cdots, n$, $\beta_0 = (\beta_{01}, \cdots, \beta_{0n})^T$, $\epsilon_n \sim N(0, \sigma_0^2 I_n)$. Let $X_n^T = (x_1, \cdots, x_n)$.

We consider the hierarchical model as follows: $Y_n | \theta, X_n, \beta, \sigma^2 \sim ind N(K_{in}^T \beta_n, \sigma^2)$ with $K_{in} = (K(x_i, x_1 | \theta), \cdots, K(x_i, x_n | \theta))$, $i = 1, \cdots, n$.

The following hierarchical is assigned to unknown parameters $\beta_n$, $\sigma^2$:

Model 1:
(i) $\beta_n | \sigma^2, A_n^2 \sim N(0, \sigma^2 \tau_n^2 A_n^2)$, $A_n^2 = diag(\lambda_1^2, \cdots, \lambda_n^2)$,
(ii) $\sigma^2 \sim IG(a/2, b/2)$,
(iii) $\lambda_i^2 \overset{i.i.d}{\sim} \pi(\lambda_0^2)$.

Remark 1 Here we assign global local shrinkage prior to the coefficient $\beta_n$, and the parameter $\tau_n^2$ is called the global shrinkage parameter. Global local shrinkage prior is widely used in high dimensional regression problem nowadays, and it can leads to posterior consistency, see Ghosh and Chakrabarti (2017), Van der Pas et al. (2014) and Song and Liang (2017). Our model is essentially a linear model, and $K_n$ in our case becomes the design matrix with coefficient $\beta_n$. We need to add some regularization conditions on $K_n$ and also on the prior distributions of $\lambda_i^2$. Our model is similar to that of Ghosh and Chakrabarti (2017), but we assume $\sigma^2$ is unknown and $K_n \neq I_n$, which makes our analysis more complicated.
With these priors we get
\[ \pi(\beta_n, \sigma^2, \Lambda_n^2 | Y_n, X_n) \]
\[ \propto (\sigma^2)^{-n-a/2-1} \pi(\Lambda_n^2) | \Lambda_n^2 |^{-1/2} \exp \left[ -b - \beta_n^T (\tau_n^{-2} \Lambda_n^{-2}) \beta_n - (Y_n - K_n \beta_n)^T (Y_n - K_n \beta_n) \right]; \]
(4)
\[ \beta_n | \sigma^2, \Lambda_n^2, Y_n, X_n \sim N((K_n^2 + \tau_n^{-2} \Lambda_n^{-2})^{-1} K_n Y_n, \sigma^2(K_n^2 + \tau_n^{-2} \Lambda_n^{-2})^{-1}); \] (5)
\[ \pi(\sigma^2, \Lambda_n^2 | Y_n, X_n) \]
\[ \propto (\sigma^2)^{-n/2-a/2-1} \pi(\Lambda_n^2) | \Lambda_n^2 |^{-1/2} \exp \left[ -b - Y_n^T (I_n - K_n (K_n^2 + \tau_n^{-2} \Lambda_n^{-2})^{-1} K_n) Y_n \right]; \]
(6)
\[ \pi(\Lambda_n^2 | Y_n, X_n) \]
\[ \propto \pi(\Lambda_n^2) | K_n^2 \Lambda_n^2 + \tau_n^{-2} I_n |^{-1/2} (b + Y_n^T [I_n - K_n (K_n^2 + \tau_n^{-2} \Lambda_n^{-2})^{-1} K_n] Y_n)^{-n/2-a/2}; \] (7)
\[ E(K_n \beta_n | Y_n, X_n) - K_n \beta_{0n} \]
\[ = E(E(K_n \beta_n | \sigma^2, \Lambda_n^2, Y_n, X_n) | Y_n, X_n) - K_n \beta_{0n} \]
\[ = E[K_n (K_n^2 + \tau_n^{-2} \Lambda_n^{-2})^{-1} K_n (Y_n - K_n \beta_{0n}) | Y_n, X_n] \]
\[ - E[K_n (K_n^2 + \tau_n^{-2} \Lambda_n^{-2})^{-1} \tau_n^{-2} \Lambda_n^{-2} \beta_{0n} | Y_n, X_n]. \] (8)

2.3 Notations

For a vector \( v \in \mathbb{R}^n \), \( \| v \|_2 = (\sum_{i=1}^{n} v_i^2)^{1/2} \) denote the \( l_2 \) norm. Let \( \lambda_{\text{max}} = \max \{ \lambda_1, \cdots, \lambda_n \} \), \( \lambda_{\text{min}} = \min \{ \lambda_1, \cdots, \lambda_n \} \), where \( \lambda_1, \cdots, \lambda_n \) are the diagonal elements of \( \Lambda_n \). \( E_0 \) denotes expectation under true model, i.e. \( E_{\beta_{0n}} \).

3. Hierarchical Bayesian Model with Bounded Kernel

In this section, we consider the case where model 1 has bounded kernel with fixed parameter \( \theta \). Before studying the property of posterior distribution, we state some regularity conditions on the matrix \( K_n \) and the true parameters \( \beta_{0n}, \sigma_0^2 \).

**Regularity conditions:**

(A1) the design matrix \( X_n \) satisfies
\[ c_1 I_n \leq K_n \leq c_2 I_n \]
for sufficiently large \( n \), where \( c_1, c_2 > 0 \) do not depend on \( n \).

(A2) \( |\beta_{0n}| \leq M \) and \( \sigma_0^2 \) does not depend on \( n \).

(A3) Let \( q_n \) be the number of nonzero elements in \( \beta_{0n} \), \( q_n = o(n) \).
Remark 2 (A1) states that the kernel $K_n$ is bounded. For Gaussian kernel with fixed parameter $\theta > 0$, if the design matrix $X_n$ satisfies the orthogonality condition, namely, $X_nX_n^T = pI_n$, $p > n$, then $K_n - I_n \to 0$ as $n \to \infty$ so that $\frac{1}{n}I_n \leq K_n \leq 2I_n$ for sufficiently large $n$. Actually we can extend conditions on $X_n$ such that the Gaussian kernel $K_n$ still satisfies (A1):

Lemma 1 If $K_n$ is a Gaussian kernel with parameter $\theta$ and $\|x_i - x_j\|^2 \geq k(n) = 2\theta \log n$ for sufficiently large $n$ if $i \neq j$, then there exists $N > 0$ such that when $n > N$, $(1 - \frac{1}{n})I_n \leq K_n \leq (1 + \frac{1}{n})I_n$.

Proof: It suffices to show that for every $c \neq 0$, $c^T K_n c \leq (1 + \frac{1}{n})c^T c$ for large $n$. But

\[
\begin{align*}
c^T K_n c \\
\leq & \sum_{i=1}^{n} c_i^2 + \sum_{1 \leq i < j \leq n} |c_i||c_j|/\exp(k(n)/\theta) \\
= & (\sum_{i=1}^{n} c_i^2 + (\sum_{i=1}^{n} |c_i|^2 - \sum_{i=1}^{n} c_i^2)/(2\exp(k(n)/\theta))) \\
\leq & [1 - \frac{1}{2\exp(k(n)/\theta)}] \sum_{i=1}^{n} c_i^2 + \frac{n \sum_{i=1}^{n} c_i^2}{2\exp(k(n)/\theta)} \\
\leq & [1 + \frac{n - 1}{2\exp(k(n)/\theta)}] \sum_{i=1}^{n} c_i^2 \\
\leq & (1 + \frac{1}{n})c^T c,
\end{align*}
\]

for sufficiently large $n$. Similarly, we have $c^T (p^{-\theta}K_n)c \geq (1 - \frac{1}{n})c^T c$.

Remark 3 Compared to Ghosh and Chakrabarti (2017), who assumed $K_n = I_n$, condition (A1) requires only boundedness of $K_n$ in both directions. Ghosh and Chakrabarti (2017) also do not impose any assumption to the true parameter $\beta_0$, while in condition (A2), we assume it is bounded. In consequence, our posterior contraction rate can be faster than the minimax rate $q_n \log(\frac{n}{q_n})$, as we will now demonstrate in the following theorems.

Theorem 1 Let $K_n$ be a kernel with fixed parameter, and conditions (A1)-(A3) hold. Consider the priors assigned to $\Lambda_n$ and $\sigma^2$ in Section 2.2. Then if $\tau_n^2 \leq n^{-\frac{3}{2}}q_n$ and

\[
\int \lambda^4 \pi(\lambda^2) d\lambda^2 < \infty,
\]

\[
E_0 \left\| E(K_n\beta_n|Y_n, X_n) - K_n\beta_0 \right\|_2^2 \leq q_n
\]
as $n \to \infty$.

Remark 4 This theorem holds for both $p \leq n$ and $p > n$ case.
Proof of Theorem 1: Denoting the rightmost side of (8) as $I - II$, it suffices to show that $E_0 \| I \|_{2,n}^2 \leq q_n$ and $E_0 \| II \|_{2,n}^2 \leq q_n$ as $n \to \infty$.

First, we prove $E_0 \| I \|_{2,n}^2 \leq q_n$. It suffices to show that

$$E_0 E[\| K_n (K_n^2 + \tau_n^{-2} \Lambda_n^{-2})^{-1} K_n (Y_n - K_n \beta_0 n) \|_{2,n}^2 | Y_n, X_n] \leq q_n.$$ 

To this end, we proceed as follows:

$$E[\| K_n (K_n^2 + \tau_n^{-2} \Lambda_n^{-2})^{-1} K_n (Y_n - K_n \beta_0 n) \|_{2,n}^2 | Y_n, X_n]$$

$$= E[(Y_n - K_n \beta_0 n)^T K_n (K_n^2 + \tau_n^{-2} \Lambda_n^{-2})^{-1} K_n^2 (K_n^2 + \tau_n^{-2} \Lambda_n^{-2})^{-1} K_n (Y_n - K_n \beta_0 n)]$$

$$\leq c_2^2 E[(Y_n - K_n \beta_0 n)^T K_n (K_n^2 + \tau_n^{-2} \Lambda_n^{-2})^{-1} K_n (Y_n - K_n \beta_0 n)]$$

$$\leq c_2^2 E[(Y_n - K_n \beta_0 n)^T K_n (K_n^2 + \tau_n^{-2} \Lambda_n^{-2})^{-1/2} (K_n^2 + \tau_n^{-2} \Lambda_n^{-2})^{-1/2} K_n (Y_n - K_n \beta_0 n)]$$

$$\leq c_2^2 E[|\lambda_{\max}^n(Y_n - K_n \beta_0 n)^T K_n (Y_n - K_n \beta_0 n)]$$

$$\leq c_2^2 \frac{c_1^4}{c_1^2} E[\lambda_{\max}^n | Y_n, X_n] \cdot \| Y_n - K_n \beta_0 n \|_{2,n}^2.$$ (9)

Next by the Schwarz inequality we have

$$E_0 c_2^4 T_n^2 \frac{c_1^4}{c_1^2} E[\lambda_{\max}^n | Y_n, X_n] \cdot \| Y_n - K_n \beta_0 n \|_{2,n}^2$$

$$\leq c_2^4 T_n^2 E_0^{1/2} (E[\lambda_{\max}^n | Y_n, X_n]) E_0^{1/2} (\| Y_n - K_n \beta_0 n \|_{2,n}^4)$$

$$\leq c_2^4 T_n^2 E_0^{1/2} (E[\lambda_{\max}^n | Y_n, X_n]) \cdot E_0^{1/2} (\lambda_n^2)^2$$ (10)

$$= c_2^4 T_n^2 E_0^{1/2} (\lambda_n^4) \cdot \sqrt{n(n + 2)} \sigma_0^4$$

$$\leq \sqrt{n} c_2^4 T_n^2 E_0^{1/2} (\lambda_n^4) \cdot \sqrt{n(n + 2)} \sigma_0^4,$$

By (9), (10), $E_0 \| I \|_{2,n}^2 \leq q_n$.

Next we show $E_0 \| II \|_{2,n}^2 \leq q_n$. 

6
Since $I_n \leq c_1^{-2}K_n^2$, $K_n^2 = K_n I_n K_n \leq c_1^{-2}K_n^4$,

$$E_0 \| II \|_{2,n}^2 \leq c_1^{-2}E_0 \left\| K_n \left( K_n^2 + \tau_n^{-2} \Lambda_n^{-2} \right)^{-1} \tau_n^{-2} \Lambda_n^{-2} \beta_{0n} \right\|_{2,n}^2 |Y_n, X_n|$$

$$c_1^{-2}E_0 \left[ \left( K_n^2 + \tau_n^{-2} \Lambda_n^{-2} \right)^{-1} \left( K_n^2 + \tau_n^{-2} \Lambda_n^{-2} \right)^{-1} \beta_{0n} \right]_{Y_n, X_n}$$

$$c_1^{-2}E_0 \left[ \left( K_n^2 + \tau_n^{-2} \Lambda_n^{-2} \right)^{-1/2} \left( K_n^2 + \tau_n^{-2} \Lambda_n^{-2} \right)^{-1} \beta_{0n} \right]_{Y_n, X_n}$$

$$c_1^{-2}E_0 \left[ \left( K_n^2 + \tau_n^{-2} \Lambda_n^{-2} \right)^{-1/2} \left( K_n^2 + \tau_n^{-2} \Lambda_n^{-2} \right)^{-1} \beta_{0n} \right]_{Y_n, X_n}$$

$$(c_2^2/c_1^2)E_0 \left[ \left( K_n^2 + \tau_n^{-2} \Lambda_n^{-2} \right)^{-1} \beta_{0n} \right]_{Y_n, X_n}$$

$$\leq c_2^2/c_1^2 \| \beta_{0n} \|_{2,n}^2 \leq q_n.$$  \hspace{1cm} (11)

The theorem follows.

**Remark 5** The assumption of finiteness of the second moment of $\lambda^2$ can be weakened. All we need is the finiteness of the $(1+\delta)^{th}$ moment of $\lambda^2$. To see this, one applies Holder’s inequality to get

$$E_0[\lambda_{max}^2 | Y_n, X_n] \cdot \| Y_n - K_n \beta_{0n} \|_{2,n}^2]$$

$$c_1^{-2}E_0 \left[ \left( K_n^2 + \tau_n^{-2} \Lambda_n^{-2} \right)^{-1/2} \left( K_n^2 + \tau_n^{-2} \Lambda_n^{-2} \right)^{-1} \beta_{0n} \right]_{Y_n, X_n}$$

$$(c_2^2/c_1^2)E_0 \left[ \left( K_n^2 + \tau_n^{-2} \Lambda_n^{-2} \right)^{-1} \beta_{0n} \right]_{Y_n, X_n}$$

$$(c_2^2/c_1^2) \| \beta_{0n} \|_{2,n}^2 \leq q_n.$$  \hspace{1cm} (12)

Since $\| Y_n - K_n \beta_{0n} \|_{2,n}^2 \sim \sigma_0^2 \lambda_n^2$,

$$E_0[\| Y_n - K_n \beta_{0n} \|_{2,n}^2] = (\sigma_0^2)^{1+\delta} (\sigma_0^2)^{1+1/\delta} = (2\sigma_0^2)^{1+\delta} \Gamma(\delta/2 + 1/\delta + 1) / \Gamma(\delta/2).$$

Using Stirling’s formula, $\Gamma(n/2 + 1/\delta + 1) / \Gamma(n/2) \leq C n^{1/\delta + 1}$, so that the second term in the right hand side of (12) is bounded above by a constant multiple of $n$, also

$$E(\lambda_{max}^{2(1+\delta)}) E_{1+\delta}^{1+\delta} (\lambda_{max}^{2(1+\delta)}) \leq n \frac{1}{1+\delta} E_{1+\delta}^{1+\delta} (\lambda_1^{2(1+\delta)}).$$  \hspace{1cm} (13)

By (12) and (13),

$$E_0[\lambda_{max}^2 | Y_n, X_n] \cdot \| Y_n - K_n \beta_{0n} \|_{2,n} \leq C n^{1+\delta} E_{1+\delta}^{1+\delta} (\lambda_1^{2(1+\delta)}).$$  \hspace{1cm} (14)

Then Theorem 1 holds with $\tau_n^2 \leq n^{-1-\delta/q_n}$. 

7
Remark 6 The assumption of \((1+\delta)\)th moment of \(\lambda^2\) holds for several distributions. Examples include the common Gamma distribution, the inverse Gaussian distribution, Student’s \(t\)-distribution with finite second moment, the inverse gamma distribution with shape parameter greater than \(1+\delta\) and the beta prime priors \(\pi(\lambda^2) \propto (\lambda^2)^{a-1}(1+\lambda^2)^{-a-b}\) with \(b > 1 + \delta\).

**Theorem 2** Let \(K_n\) be a kernel with fixed parameter, and conditions (A1)-(A3) hold. Consider the priors assigned to \(\Lambda_n\) and \(\sigma^2\) as in Section 2.3. Then if \(\tau_n^2 \leq n^{-\frac{2}{3}}q_n\) and

\[
\int \lambda^4 \pi(\lambda^2)d\lambda^2 < \infty,
\]

then

\[
E_0\{tr[V(K_n\beta_n|Y_n, X_n)]\} \leq q_n
\]
as \(n \to \infty.

**Proof of Theorem 2:** By (6) we have \(E(\sigma^2|\Lambda_n, Y_n, X_n) = \frac{b+Y_n^T(I_n-K_n(K_n^2+\tau_n^{-2}\Lambda_n^{-2})^{-1}K_n)Y_n}{n+a-2}\),

\[
tr[V(K_n\beta_n|Y_n, X_n)]
= tr[E[V(K_n\beta_n|\sigma^2, \Lambda_n, Y_n, X_n)|Y_n, X_n]]
+ tr[V[E(K_n\beta_n|\sigma^2, \Lambda_n, Y_n, X_n)]|Y_n, X_n]
= tr[E\left[\frac{b+Y_n^T(I_n-K_n(K_n^2+\tau_n^{-2}\Lambda_n^{-2})^{-1}K_n)Y_n}{n+a-2}K_n(K_n^2+\tau_n^{-2}\Lambda_n^{-2})^{-1}K_n\right]Y_n, X_n]
+ tr[V(K_n(K_n^2+\tau_n^{-2}\Lambda_n^{-2})^{-1}K_n|Y_n, X_n]
= III + IV, say.

III \leq tr[E\left[\frac{b+Y_n^TY_n}{n+a-2}Y_n\right]_{\Lambda_n^2 \max}\n \leq n_2^2 \tau_n^{-2} E[\lambda_{\max}^2|Y_n, X_n] \frac{b+Y_n^TY_n}{n+a-2}
\leq n_2^2 \tau_n^{-2} E[\lambda_{\max}^2|Y_n, X_n] \frac{b+2(Y_n-K_n\beta_0)\beta_0 + 2\beta_0^T K_n^2 \beta_0}{n+a-2}
\leq n_2^2 \tau_n^{-2} E[\lambda_{\max}^2] \frac{b+y_n^TY_n}{n+a-2}
\leq n_2^2 \tau_n^{-2} E[\lambda_{\max}^2] \frac{b+2(Y_n-K_n\beta_0)^T(Y_n-K_n\beta_0)}{n+a-2}
\leq n_2^2 \tau_n^{-2} E_0^{1/2}[E\lambda_{\max}^4] \frac{b+2y_n^TY_n}{n+a-2}
\leq n_2^2 \tau_n^{-2} E_0^{1/2}[E\lambda_{\max}^4] \frac{b+2q_n^2}{n+a-2}
\leq n_2^2 \tau_n^{-2} E_0^{1/2}[E\lambda_{\max}^4] \frac{b+2q_n^2}{n+a-2}
\leq n_2^2 \tau_n^{-2} E_0^{1/2}[E\lambda_{\max}^4] \frac{b+2q_n^2}{n+a-2}
\leq n_2^2 \tau_n^{-2} E_0^{1/2}[E\lambda_{\max}^4] \frac{b+2q_n^2}{n+a-2}
\leq n_2^2 \tau_n^{-2} E_0^{1/2}[E\lambda_{\max}^4] \frac{b+2q_n^2}{n+a-2}
\leq q_n.

By the Schwarz inequality,

\[
E_0III \leq n_2^2 \tau_n^{-2} E_0^{1/2}[E\lambda_{\max}^4] \frac{b+2y_n^TY_n}{n+a-2}
+ 2n_2^2 \tau_n^{-2} E_0^{1/2}[E\lambda_{\max}^4] E_0^{1/2}[\frac{(Y_n-K_n\beta_0)\beta_0+2\beta_0^T K_n^2 \beta_0}{n+a-2}]
\leq n_2^2 \tau_n^{-2} E_0^{1/2}[E\lambda_{\max}^4] \frac{b+2y_n^TY_n}{n+a-2}
\leq n_2^2 \tau_n^{-2} E_0^{1/2}[E\lambda_{\max}^4] \frac{b+2q_n^2}{n+a-2}
\leq q_n.
\]
\[ IV = \text{tr} V[K_n(K_n^2 + \tau_n^{-2} \Lambda_n^{-2})^{-1} K_n(Y_n - K_n \beta_{0n} + K_n \beta_{0n})|Y_n, X_n] \]
\[ \leq 2 \text{tr} V[K_n(K_n^2 + \tau_n^{-2} \Lambda_n^{-2})^{-1} K_n(Y_n - K_n \beta_{0n})|Y_n, X_n] \]
\[ + 2 \text{tr} V[K_n(K_n^2 + \tau_n^{-2} \Lambda_n^{-2})^{-1} K_n^2 \beta_{0n}|Y_n, X_n]. \]  

The 1st term in the RHS of (18)
\[ \leq 2 E[\|K_n(K_n^2 + \tau_n^{-2} \Lambda_n^{-2})^{-1} K_n(Y_n - K_n \beta_{0n})\|_2^2|Y_n, X_n]. \]

Then by (9), (10), we have
\[ E_0\{\text{tr} V[K_n(K_n^2 + \tau_n^{-2} \Lambda_n^{-2})^{-1} K_n(Y_n - K_n \beta_{0n})|Y_n, X_n]\} \leq q_n. \]  

The 2nd term in the RHS of (18)
\[ \leq 2 E[\|K_n(K_n^2 + \tau_n^{-2} \Lambda_n^{-2})^{-1} K_n^2 \beta_{0n}\|_2^2|Y_n, X_n] \]
\[ \leq 2 \frac{c_2}{c_1} \beta_{0n}^T K_n^2(K_n^2 + \tau_n^{-2} \Lambda_n^{-2})^{-1} K_n^2 \beta_{0n} \]
\[ = 2 \frac{c_2}{c_1} \beta_{0n}^T K_n^2(K_n^2 + \tau_n^{-2} \Lambda_n^{-2})^{-1/2}(K_n^2 + \tau_n^{-2} \Lambda_n^{-2})^{-1/2} K_n^2 \beta_{0n} \]
\[ \leq 2 (\frac{c_2}{c_1})^2 \beta_{0n}^T K_n^2(K_n^2 + \tau_n^{-2} \Lambda_n^{-2})^{-1} K_n^2 \beta_{0n} \]
\[ \leq 2 (\frac{c_2}{c_1})^2 \beta_{0n}^T K_n^2 K_n^2 \beta_{0n} \]
\[ \leq 2 \frac{c_4}{c_1} \beta_{0n}^2 \|_{2, n} \leq q_n. \]

Hence,
\[ E_0\{\text{tr} V[K_n(K_n^2 + \tau_n^{-2} \Lambda_n^{-2})^{-1} K_n^2 \beta_{0n}|Y_n, X_n]\} \leq q_n. \]  

(20)

The theorem follows from (15)-(20).

By Theorems 1 and 2, we immediately get

**Corollary 1** If \( K_n \) is a kernel with fixed parameter, and conditions (A1)-(A3) hold, with the prior assigned to \( \Lambda_n \) and \( \sigma^2 \) in model 1, if \( \tau_n^2 \leq n^{-\frac{3}{2}} q_n \) and
\[ \int \lambda^4 \pi(\lambda^2) d\lambda^2 < \infty, \]

then
\[ E_0 P(\|K_n \beta_n - K_n \beta_{0n}\|_2^2|Y_n, X_n) \geq M_n q_n|Y_n, X_n| \to 0 \]
as \( n \to \infty \), where \( M_n \to \infty \) as \( n \to \infty. \)

In particular, one may take \( M_n = \log(n/q_n) \) to get the asymptotic minimax contraction bound.
4. Hierarchical Bayesian Model with Polynomial Kernel

For a polynomial kernel, we can not apply Theorem 1 directly, because the regularity condition (A1) does not generally hold. For example, for polynomial kernel with fixed parameter \( \theta > 0 \), if the design matrix \( X_n \) satisfies the orthogonality condition, namely, \( X_n X_n^T = pI_n \), then \( p^{-\theta} K_n \rightarrow I_n \) as \( n \rightarrow \infty \) so that \( \frac{1}{2} p^{-\theta} I_n \leq K_n \leq 2p^{-\theta} I_n \) for sufficiently large \( n \), which does not satisfy condition (A1). In this section, we consider the case when the design matrix \( X_n \) satisfies \( t_1(n) I_n \leq K_n \leq t_2(n) I_n \), \( t_2(n)/t_1(n) = O(1) \), where \( t_1(n) \) and \( t_2(n) \) are functions depending solely on \( n \).

We have the following posterior contraction result for polynomial kernels.

**Theorem 3** If \( K_n \) is a kernel with fixed parameter, and conditions (A2),(A3) hold, with the prior assigned to \( \Lambda_n \) and \( \sigma^2 \) in model 1, if \( t_1(n) I_n \leq K_n \leq t_2(n) I_n \), \( t_2(n)/t_1(n) = O(1) \), then

\[
\int \lambda^4 \pi(\lambda^2) d\lambda^2 < \infty,
\]

and

\[
E_0 \| E(K_n \beta_n|Y_n, X_n) - K_n \beta_{0n} \|_{2,n}^2 \leq q_n t_2^2(n)
\]

as \( n \rightarrow \infty \).

**Proof of Theorem 3**: This proof is almost the same as of Theorem 1. It suffices to show that \( E_0 \| I \|_{2,n}^2 \leq q_n t_2^2(n) \) and \( E_0 \| II \|_{2,n}^2 \leq q_n t_2^2(n) \) as \( n \rightarrow \infty \).

Substituting \( c_1 \) and \( c_2 \) in Theorem 1 by \( t_1(n) \) and \( t_2(n) \), we get

\[
E_0 \| I \|_{2,n}^2 \leq \sqrt{n} \frac{t_2^2(n)/t_1^2(n)}{t_1^2(n)} E_0^{1/2}(\lambda_1^2) \cdot \sqrt{n(n + 2)} \sigma_0^2 \leq q_n t_2^2(n)
\]

(21)

and

\[
E_0 \| II \|_{2,n}^2 \leq (t_2^2(n)/t_1^2(n))\|\beta_{0n}\|_{2,n}^2 \leq q_n t_2^2(n).
\]

(22)

**Theorem 4** Let \( K_n \) be a kernel with fixed parameter, and conditions (A2) and (A3) hold. Then with the same priors assigned to \( \Lambda_n \) and \( \sigma^2 \) in Section 2.2, if \( t_1(n) I_n \leq K_n \leq t_2(n) I_n \), \( t_2(n)/t_1(n) = O(1) \), \( t_2^2(n) \approx nq_n^{-1} \), \( \tau_n^2 = q_n n^{-3/2} \) and \( \int \lambda^4 \pi(\lambda^2) d\lambda^2 < \infty \), then

\[
E_0 \{ tr[V(K_n \beta_n|Y_n, X_n)] \} \leq q_n t_2^2(n)
\]

as \( n \rightarrow \infty \).

**Proof of Theorem 4**: This proof is almost the same as of theorem 2. Substitute \( c_1 \), \( c_2 \) in theorem 2 by \( t_1(n) \), \( t_2(n) \).

Combining Theorems 3 and 4 we get
Corollary 2 Let $K_n$ be a kernel with fixed parameter, and conditions (A2) and (A3) hold. Consider the same priors assigned to $\Lambda_n$ and $\sigma^2$ as in Section 2.2. If $t_1(n)I_n \leq K_n \leq t_2(n)I_n$, $t_2(n)/t_1(n) = O(1)$, $t_2^2(n) < nq_n^{-1}$, $\tau_n^2 = q_n n^{-3/2}$ and

$$\int \lambda^4 \pi(\lambda^2) d\lambda^2 < \infty,$$

then

$$E_0 P(\|K_n\beta_n - K_n\beta_{0n}\|_2^2 \geq q_n t_2^2(n)|Y_n, X_n) \to 0$$

as $n \to \infty$.

Remark 7 For polynomial kernels with fixed parameters, if the design matrix is approximately orthogonal, then we still have $t_1(n)I_n \leq K_n \leq t_2(n)I_n$, $t_2(n)/t_1(n) = O(1)$. Theorems 3, 4 and Corollary 2 hold if $p^\theta \leq \sqrt{nq_n^{-1}}$. Actually we have the following lemma which describes the behavior of the kernel $K_n$ when the design matrix is approximately orthogonal.

Lemma 2 Let $K_n$ be a polynomial kernel with parameter $\theta \in [a_L, a_U]$, $a_L > 1/2$, and the design matrix $X_n$ satisfies

$$|x_i \cdot x_j + 1/p - 1| \leq \frac{1}{h(n)}, |x_i \cdot x_j + 1/p| \leq \frac{1}{k(n)}, 1 \leq i \neq j \leq n,$$

$h(n) = 2a_U \cdot n$, $k(n) = n^4$, for sufficiently large $n$. Then there exists $N > 0$ such that when $n > N$, $(1 - \frac{1}{n})I_n \leq p^{-\theta} K_n \leq (1 + \frac{1}{n})I_n$ for all $\theta \in [a_L, a_U]$.

Proof: It suffices to show that for every $c \neq 0$, $c^T (p^{-\theta} K_n) c \leq (1 + \frac{1}{n}) c^T c$ for large $n$. But

$$c^T (p^{-\theta} K_n) c \leq \sum_{i=1}^n c_i^2 (1 + \frac{1}{h(n)})^\theta + \sum_{1 \leq i \neq j \leq n} |c_i||c_j|/k^\theta(n)$$

$$= (1 + \frac{1}{h(n)})^\theta \sum_{i=1}^n c_i^2 + \frac{1}{2k^\theta(n)} \sum_{i=1}^n (\sum_{j=1}^n |c_i|)^2 - \sum_{i=1}^n c_i^2/2k^\theta(n)$$

$$\leq ((1 + \frac{1}{h(n)})^\theta - \frac{1}{2k^\theta(n)}) \sum_{i=1}^n c_i^2 + \frac{n \sum_{i=1}^n c_i^2}{2k^\theta(n)}$$

$$\leq ((1 + \frac{1}{h(n)})^\theta - \frac{1}{2n^\theta} + \frac{1}{2n^\theta} - \frac{1}{2n^\theta - 1}) \sum_{i=1}^n c_i^2$$

$$\leq (1 + \frac{1}{n}) c^T c, \text{ (since } \theta > \frac{1}{2}).$$

Similarly, we have $c^T (p^{-\theta} K_n) c \geq (1 - \frac{1}{n}) c^T c$.

Although we have to assume $p < n$ to get posterior contraction results for polynomial kernels, we can still get posterior consistency for the $p > n$ case for polynomial kernels.
**Theorem 5** Let $K_n$ be a kernel with fixed parameter, and conditions (A2) and (A3) hold. Consider the same priors assigned to $\Lambda_n$ and $\sigma^2$ as in Section 2.2. If $t_1(n)I_n \leq K_n \leq t_2(n)I_n$, $t_2(n)/t_1(n) = O(1)$, if $t_1(n) \geq \sqrt{q_n n^{3/2}}$, $\tau_n^2 = \sqrt{q_n t_1^{-2}(n)n^{-\frac{3}{2}}}$,

$$\int \lambda^4 \pi(\lambda^2)d\lambda^2 < \infty, \quad \int \lambda^{-2} \pi(\lambda^2)d\lambda^2 < \infty,$$

then

$$E_0 P(\|\beta_n - \beta_{0n}\|_{2,n}^2 \geq \sqrt{q_n t_1^{-2}(n)n^{\frac{3}{2}}}|Y_n, X_n) \to 0$$

as $n \to \infty$.

**Remark 8** For polynomial kernels, condition $t_1(n) \geq \sqrt{q_n n^{3/2}}$ means $p \geq (q_n n^{3/2})^{\frac{1}{3}}$.

**Proof of Theorem 5:** We prove this theorem by combining the next two lemmas.

**Lemma 3** Let $K_n$ be a kernel with a fixed parameter, and assume conditions (A2) and (A3) to hold. Then with the prior assigned to $\Lambda_n$ and $\sigma^2$ in the model given in Section 2.2, if $t_1(n)I_n \leq K_n \leq t_2(n)I_n$, $t_2(n)/t_1(n) = O(1)$, $t_1(n) \geq \sqrt{q_n n^{3/2}}$, $\tau_n^2 = \sqrt{q_n t_1^{-2}(n)n^{-\frac{3}{2}}}$,

$$\int \lambda^4 \pi(\lambda^2)d\lambda^2 < \infty, \quad \int \lambda^{-2} \pi(\lambda^2)d\lambda^2 < \infty,$$

then

$$E_0 \| E(\beta_n|Y_n, X_n) - \beta_{0n} \|_{2,n}^2 \leq \sqrt{q_n t_1^{-2}(n)n^{\frac{3}{2}}}$$

as $n \to \infty$.

**Proof of Lemma 3:** Since we have

$$E(\beta_n|Y_n, X_n) - \beta_{0n} = E(E(\beta_n|\sigma^2, \Lambda_n^2, Y_n, X_n)|Y_n, X_n) - \beta_{0n}$$

$$= E[(K_n^2 + \tau_n^{-2}\Lambda_n^{-2})^{-1}K_n(Y_n - K_n\beta_{0n})|Y_n, X_n]$$

$$- E[(K_n^2 + \tau_n^{-2}\Lambda_n^{-2})^{-1}\tau_n^{-2}\Lambda_n^{-2}\beta_{0n}|Y_n, X_n]$$

$$= V_1 - V_2 (say).$$

It suffices to show that $E_0 \| V_1 \|_{2,n}^2 \leq \sqrt{q_n t_1^{-2}(n)n^{\frac{3}{2}}}$ and $E_0 \| V_2 \|_{2,n}^2 \leq \sqrt{q_n t_1^{-2}(n)n^{\frac{3}{2}}}$ as $n \to \infty$.

First, consider $E_0 \| V_1 \|_{2,n}^2 \leq \sqrt{q_n t_1^{-2}(n)n^{\frac{3}{2}}}$. Similar to (9),(10) in the proof of theorem 1, we get

$$E_0 \| V_1 \|_{2,n}^2 \leq \sqrt{t_1^{-2}(n)\tau_n^2}E_0^{1/2}(\lambda_1^2) \cdot \sqrt{n(n+2)\sigma_0^4} \leq \sqrt{q_n t_1^{-2}(n)n^{\frac{3}{2}}}.$$

(24)
Next we show \( E_0 \| V I \|_{2,n}^2 \leq \sqrt{q_n t_1^{-2}(n) n^\frac{3}{2}} \).

\[
E_0 \| V_2 \|_{2,n}^2 \\
\leq E_0 [\| (K_n^2 + \tau_n^{-2} \Lambda_n^{-2})^{-1} \tau_n^{-2} \Lambda_n^{-2} \beta_{0n} \|_{2,n}^2 | Y_n, X_n ] \\
= E_0 [\beta_{0n}^T (K_n^2 + \tau_n^{-2} \Lambda_n^{-2} - 1/2 (K_n^2 + \tau_n^{-2} \Lambda_n^{-2})^{-1} (K_n^2 + \tau_n^{-2} \Lambda_n^{-2}) - 1/2 (\tau_n^{-2} \Lambda_n^{-2}) \beta_{0n} | Y_n, X_n ] \\
\leq 1/t_1^2(n) E_0 [\beta_{0n}^T (\tau_n^{-2} \Lambda_n^{-2}) (K_n^2 + \tau_n^{-2} \Lambda_n^{-2})^{-1} (\tau_n^{-2} \Lambda_n^{-2}) \beta_{0n} | Y_n, X_n ] \\
\leq 1/t_1^2(n) E_0 [\beta_{0n}^T (\tau_n^{-2} \Lambda_n^{-2}) \beta_{0n} | Y_n, X_n ] \\
\leq \frac{M^2 q_n}{t_1^2(n) t_n^{-2}} E [\lambda_1^{-2} | Y_n, X_n ] = \frac{M^2 q_n}{t_1^2(n) t_n^{-2}} E (\lambda_1^{-2}) \leq \sqrt{q_n t_1^{-2}(n) n^\frac{3}{2}}.
\]

(25)

**Lemma 4** If \( K_n \) is a kernel with fixed parameter, and conditions (A2),(A3) hold, with the prior assigned to \( \Lambda_n \) and \( \sigma^2 \) in model 1, if \( t_1(n) I_n \leq K_n \leq t_2(n) I_n \), \( t_2(n)/t_1(n) = O(1) \), if \( t_1(n) \geq \sqrt{q_n n^{-3/2}} \), \( \tau_n^2 = \sqrt{q_n t_1^{-2}(n) n^{-3/2}} \) and

\[
\int \lambda^4 \pi(\lambda^2) d\lambda < \infty, \quad \int \lambda^{-2} \pi(\lambda^2) d\lambda < \infty
\]

then

\[
E_0 [ \operatorname{tr} [V(\beta_n | Y_n, X_n)]] \leq \sqrt{q_n t_1^{-2}(n) n^\frac{3}{2}}
\]

as \( n \to \infty \).

**Proof of Lemma 4:** By the same method in theorem 2, we can prove this lemma. There is only one step is slightly different from theorem 2, equation (20).

\[
E_0 [ \operatorname{tr} [V(\beta_n^2 | Y_n, X_n)]] = E_0 [ \operatorname{tr} [V(\beta_n | Y_n, X_n)]] \\
\leq E_0 [ \beta_{0n}^T E [\Lambda_n^{-2} (K_n^2 + \Lambda_n^{-2})^{-1} \Lambda_n^{-2} | Y_n, X_n ] | \beta_{0n} ] \\
\leq \frac{1}{t_1^2(n)} E_0 [ \beta_{0n}^T E [\Lambda_n^{-2} | Y_n, X_n ] | \beta_{0n} ] \\
\leq \frac{1}{t_1^2(n)} M^2 q_n E [\lambda_1^{-2} | Y_n, X_n ] \\
= \frac{1}{t_1^2(n)} M^2 q_n E [\lambda_1^{-2}] \leq \sqrt{q_n t_1^{-2}(n) n^\frac{3}{2}}.
\]

(26)

5. Discussion

Tipping (2001) pointed out that RVM is a Gaussian process model. Van der Vaart and Van Zanten (2008) and Ghosal and Van der Vaart (2017), obtained several posterior concentration results for Gaussian process models. They considered estimating a regression function \( f \) based on observations \( Y_1, \ldots, Y_n \) in a normal regression model with fixed covariates
\( Y_{in} = f(x_i) + \epsilon_i \), where \( \epsilon_i \overset{i.i.d}{\sim} N(0, \sigma_i^2) \) and the covariates \( x_1, \ldots, x_n \) are fixed elements from a set \( \mathcal{X} \).

A prior on \( f \) is induced by setting \( f(x) = W_x \), for a Gaussian process (\( W_x : x \in \mathcal{X} \)). Any Gaussian element in a separable Banach space can be expanded as an infinite series \( \sum_i Z_i h_i \) for i.i.d standard normal variables \( Z_i \) and elements \( h_i \) from its RKHS. Van der Vaart and Van Zanten (2008) truncated this infinite series at a sufficient high level to get a new Gaussian process prior. If this truncated series converges to the infinite series quickly, then by Theorem 2.2 in Van der Vaart and Van Zanten (2008), the same posterior rate of contraction is attained. Since finite sums may be easier to handle, it is interesting to investigate special expansions and the number of terms that need to be retained in order to obtain the same contraction rate. Van der Vaart and Van Zanten (2008) illustrated this by an example of the truncated wavelet expansion of functions in \( L_2([0,1]^d) \). Ghosal and Van der Vaart (2007) considered the truncated B-spline expansion in their Theorem 12. These truncated series are quite similar to our model if set \( p = d \) fixed, \( K_n = I_n \) and the prior \( \beta_n \sim N(0, I_n) \). However in their case, the number of terms in the random series is \( O(n^\alpha) \), \( \alpha < 1 \), while ours is \( n \). Adding global shrinkage parameter \( \tau_n \) to accommodate sparsity seems reasonable. Also, the Gaussian process prior related to RVM is data dependent, which is likely to add flexibility to prediction.

In our model, we assume the true model can be written explicitly as \( f_0(x) = \sum_{j=1}^{n}\beta_j K(x, x_j) \), which is dependent on the \( x_i \). A natural question is how a posterior contraction result holds if \( \sum_{j=1}^{n}\beta_j K(x, x_j) \) is just a good approximation of \( f_0(x) \) like the condition (7.10) in Ghosal and Van der Vaart (2007).

Also, the regularity condition (A2) is a strong assumption. One needs to investigate a possible posterior contraction result without this condition.

Acknowledgments
We would like to thank the referee for his many valuable comments which improved the paper considerably.
