Abstract

Estimation of signal-to-noise ratios and noise variances in high-dimensional linear models have important applications in statistical inference, hyperparameter selection, and heritability estimation in genomics. One common approach in practice is maximum likelihood estimation under random effects models. This paper aims to conduct model misspecification analysis on the consistency of this method, in which the true model only has fixed effects. Assume that the ratio between the number of samples and features converges to a nonzero constant, our results provide conditions on the design matrices under which random effects model based maximum likelihood estimation is asymptotically consistent in estimating the SNR and noise variance. Our model misspecification analysis also extends to the high-dimensional linear models with feature groups, in which group SNR estimation has important applications such as tuning parameter selection for group ridge regression.

1 Introduction

In high-dimensional linear models, noise variance and signal-to-noise ratio (SNR) estimations are important statistical problems with applications in statistical inference and tuning parameter selection in ridge regression or LASSO, see e.g. Sun and Zhang (2012); Dicker (2014); Janson et al. (2017); Dicker and Erdogdu (2016). They also have applications in genome wide association studies (GWAS), which aims to detect risky genetic variants through examination of association between complex traits and millions of genetic variants. The contribution of genetic variance to phenotypic variance is usually explained by heritability (Falconer, 1961), a measure relies on variance components estimation.

Besides various methods of moments proposed for SNR and noise variance estimation (Dicker, 2014; Janson et al., 2017), a standard approach commonly used in practice is maximum likelihood estimation based on linear mixed effects models, or linear random effects models if no fixed effects included, for which the asymptotic analysis dates back to Hartley and Rao (1967). In recent years, high-dimensional linear random effects models have been used in GWAS for heritability estimation (Yang et al., 2011; Gusev et al., 2014; Steinsaltz et al., 2018). Asymptotic analysis for high-dimensional linear mixed effects models has been conducted in Jiang (1996), in which the number of variables is allowed to increase
as the number of samples increases. Several textbooks have been devoted to introducing the models, methods and applications of linear mixed models and their extensions, see, e.g., Rao (1997); Jiang (2007).

In spite of recent applications of linear random effects models in GWAS, their reliability in estimating heritability has been questioned in the literature (De los Campos et al., 2015; Ma and Dicker, 2019). From a theoretical perspective, it is worthwhile to figure out the conditions under which random effects models are able to yield consistent estimates of the SNR and noise variance, even the true model is quite different from the postulated one. A series of theoretical works have already been devoted to such model misspecification analysis. A notable recent work is Jiang et al. (2016), in which the misspecification analysis is conducted under sparse random effects models. Similar model misspecification analysis has also been conducted in Dicker and Erdogdu (2017) by a novel tool of uniform Hanson-Wright inequality. In the case that the design matrix consists of i.i.d. Gaussian entries, it has been proven in Dicker and Erdogdu (2016) that estimation under linear random effects models is asymptotically consistent when the ground truth is a standard linear fixed effects model. Their argument is basically by rotational invariance of Gaussianity and an equivalence between fixed effects models and correlated random effects models, and the misspecification analysis based on the latter has already been conducted in Dicker and Erdogdu (2017).

Our first result follows the above line of research. Similar to Dicker and Erdogdu (2016), we also studied the consistency of linear random effects model where the ground truth is a fixed effects model, but we relax their Gaussian assumption in the design matrix components. This condition relaxation requires very different technical ideas. We actually need to follow the analytical framework in Jiang et al. (2016), but specific analysis is quite different since we assume the true model has general fixed effects, whereas the linear model in Jiang et al. (2016) has sparse random effects. Our second result extends the misspecification analysis to high-dimensional linear models with feature groups according to which the design matrix is partitioned. Then, in the postulated linear random effects models, the random effects corresponding to different groups are modeled with different variances. Note that consistency of linear random effects models with feature groups is well-studied in the literature (Jiang, 1996), but misspecification analysis for such models is little-studied in the literature to our knowledge. In fact, group SNR estimation under linear models with feature groups has important applications in partitioned heritability estimation (Stergachis et al., 2013; Gusev et al., 2014), as well as tuning parameters selection in group regularized ridge regression (Ignatiadis and Lolas, 2020).

1.1 Maximum Likelihood Estimation under Linear Random Effects Models

We first consider the standard high-dimensional linear model:

\[ y = Z\beta + \epsilon, \]

where \( Z \) is an \( n \times p \) design matrix in which \( p \) is allowed to be greater than \( n \), \( \beta \) is the vector of regression coefficients, \( \epsilon \) is the vector of i.i.d. noise with mean zero and variance
\(\sigma_0^2\), and \(y\) is the response vector. Our goal is to estimate the noise variance \(\sigma_0^2\) as well as the signal-to-noise ratio (SNR) parameter \(\gamma_0 := \|\beta\|^2 / \sigma_0^2\).

One standard method in the literature to estimate noise variance as well as SNR is the Gaussian random effects maximum likelihood estimation, in which the vector of regression coefficients is modeled as \(\beta = p^{-1/2}\alpha\), where \(\alpha\) is assumed to consist of i.i.d. \(\mathcal{N}(0, \sigma_\alpha^2)\) variables. In addition, the i.i.d. noise is assumed to follow the distribution \(\mathcal{N}(0, \sigma_\varepsilon^2)\). It is clear that \(\sigma_0^2\) is the true value of \(\sigma_\varepsilon^2\), \(\|\beta\|^2\) is the true value of \(\sigma_\alpha^2\), and \(\gamma_0 = \|\beta\|^2 / \sigma_0^2\) is the true value of \(\gamma := \sigma_\alpha^2 / \sigma_\varepsilon^2\). Detailed derivation for the MLE of \((\sigma_\varepsilon^2, \sigma_\alpha^2)\) under linear random effects models can be found in Jiang (2007). Here we give the log-likelihood function directly

\[
l(\sigma_\varepsilon^2, \sigma_\alpha^2) = c - \frac{1}{2} \log \det(\Omega) - \frac{1}{2} y^\top\Omega^{-1}y, \tag{2}\]

where \(c\) is a constant, and

\[
\Omega = \Omega(\sigma_\varepsilon^2, \sigma_\alpha^2) := \sigma_\varepsilon^2 I_n + \frac{\sigma_\alpha^2}{p} ZZ^\top := \sigma_\varepsilon^2 V_\gamma, \quad \text{where } V_\gamma = I_n + \frac{\gamma}{p} ZZ^\top. \tag{3}\]

The MLE is thereby \((\hat{\sigma}_\varepsilon^2, \hat{\sigma}_\alpha^2) = \arg \max_{\sigma_\varepsilon^2 > 0, \sigma_\alpha^2 > 0} l(\sigma_\varepsilon^2, \sigma_\alpha^2)\).

By taking the partial derivatives of the log-likelihood with respect to \(\sigma_\varepsilon^2\) and \(\sigma_\alpha^2\) to obtain the score functions, the resulting likelihood equations are as follows:

\[
\begin{cases}
S_{\sigma_\varepsilon^2}(\sigma_\varepsilon^2, \sigma_\alpha^2) := \frac{1}{2} y^\top(\Omega^{-1} - \frac{1}{2} \text{trace}(\Omega^{-1})) = 0 \\
S_{\sigma_\alpha^2}(\sigma_\varepsilon^2, \sigma_\alpha^2) := \frac{1}{2} y^\top(\Omega^{-1} - \frac{1}{2} \text{trace}(\Omega^{-1})) = 0.
\end{cases} \tag{4}\]

The above set of equations can yield a single equation on the signal-to-noise ratio parameter \(\gamma = \frac{\sigma_\alpha^2}{\sigma_\varepsilon^2}\):

\[
\Delta(\gamma) := y^\top B\gamma y = 0. \tag{5}\]

where

\[
B\gamma := \frac{V_\gamma^{-1} (\frac{1}{p} ZZ^\top) V_\gamma^{-1} - V_\gamma^{-2}}{\text{trace}(V_\gamma^{-1})}.
\tag{6}\]

Let \(\hat{\gamma}\) be a solution to (5), which is the MLE of the true SNR \(\gamma_0 = \|\beta\|^2 / \sigma_0^2\).

With an SNR estimate \(\hat{\gamma}\), the first likelihood equation in (4) gives the MLE of \(\sigma_\varepsilon^2\) as

\[
\hat{\sigma}_\varepsilon^2 = \frac{y^\top V_\hat{\gamma}^{-2} y}{\text{trace}(V_\hat{\gamma}^{-1})}.
\]

For simplicity of theoretical analysis, we consider the following simpler estimate

\[
\hat{\sigma}_\varepsilon^2 = \frac{1}{n} y^\top V_\hat{\gamma}^{-1} y. \tag{7}\]

We aim to study the consistency of \(\hat{\gamma}\) defined in (5) and \(\hat{\sigma}_\varepsilon^2\) in (7) under model misspecification: If the true model is the fixed effect linear model (1), are \(\hat{\gamma}\) and \(\hat{\sigma}_\varepsilon^2\) consistent estimates of \(\gamma_0 = \|\beta\|^2 / \sigma_0^2\) and \(\sigma_0^2\), respectively? What conditions guarantee such consistency? These questions will be investigated throughout the paper.
1.2 Extension to Linear Models with Feature Groups

Let’s consider an extension of the standard linear model (1) to the case where the design matrix is partitioned according to several feature groups. To be specific, assume the linear model is represented as

\[ y = \sum_{i=1}^{s} Z_i \beta_i + \varepsilon \]  

where \( Z_i \in \mathbb{R}^{n \times p_i} \) is the design matrix corresponding to the \( i \)-th feature group, and \( \beta_i \in \mathbb{R}^{p_i} \) is the corresponding vector of regression coefficients, so the design matrix \( Z = [Z_1, \ldots, Z_s] \) is partitioned into \( s \) feature groups. In this case, besides estimating \( \sigma_0^2 \), we are interested in estimating the group SNRs \( \gamma_{0i} := \|\beta_i\|^2/\sigma_0^2 \) for \( i = 1, \ldots, s \). As aforementioned, this problem has interesting applications in tuning parameters selection in group regularized ridge regression (Ignatiadis and Lolas, 2020).

As with the standard case, we consider a linear random effects model corresponding to (8). Assume the i.i.d. noise follows \( N(0, \sigma^2) \), and replace \( \beta_i \) with \( p_i^{-\frac{1}{2}} \alpha_i \), where \( \alpha_i \) consists of i.i.d. Gaussian random variables with distribution \( N(0, \sigma_0^2) \) for \( i = 1, \ldots, s \). Then, the linear fixed effects model (8) with feature groups is remodeled into a random effects model

\[ y = \sum_{i=1}^{s} p_i^{-\frac{1}{2}} Z_i \alpha_i + \varepsilon. \]

As with the standard case, the true values of the parameters \( \sigma_\varepsilon^2, \sigma_{\alpha_i}^2 \) and \( \gamma_i = \sigma_{\alpha_i}^2/\sigma_\varepsilon^2 \) are \( \sigma_\varepsilon^2, \|\beta_i\|^2 \) and \( \gamma_{0i} = \|\beta_i\|^2/\sigma_0^2 \) respectively.

Linear random effects models with feature groups have been well studied in the literature; see also Jiang (1996). As with the standard case, i.e., \( s = 1 \), the log-likelihood function is

\[ l(\sigma_\varepsilon^2, \sigma_{\alpha_1}^2, \ldots, \sigma_{\alpha_s}^2) = c - \frac{1}{2} \log \det(\Omega) - \frac{1}{2} y^\top \Omega^{-1} y, \]  

where

\[ \Omega = \Omega(\sigma_\varepsilon^2, \sigma_{\alpha_1}^2, \ldots, \sigma_{\alpha_s}^2) := \sigma_\varepsilon^2 I_n + \sum_{i=1}^{s} \frac{\sigma_{\alpha_i}^2}{p_i} Z_i Z_i^\top := \sigma_\varepsilon^2 V_\gamma, \]

and

\[ V_\gamma = I_n + \sum_{i=1}^{s} \frac{\gamma_i}{p_i} Z_i Z_i^\top. \]

Taking the partial derivatives with respect to the variance parameters, we obtain the score functions and the likelihood equations:

\[
\begin{align*}
S_{\sigma_\varepsilon^2}(\sigma_\varepsilon^2, \sigma_{\alpha_1}^2, \ldots, \sigma_{\alpha_s}^2) &:= \frac{1}{2} y^\top \Omega^{-2} y - \frac{1}{2} \text{trace}(\Omega^{-1}) = 0 \\
S_{\sigma_{\alpha_i}^2}(\sigma_\varepsilon^2, \sigma_{\alpha_1}^2, \ldots, \sigma_{\alpha_s}^2) &:= \frac{1}{2} y^\top \Omega^{-1} \left( \frac{1}{p_i} Z_i Z_i^\top \right) \Omega^{-1} y - \frac{1}{2} \text{trace} \left( \Omega^{-1} \frac{1}{p_i} Z_i Z_i^\top \right) = 0, \quad 1 \leq i \leq s.
\end{align*}
\]

Then, the above set of equations gives likelihood equations for \( \gamma = (\gamma_1, \ldots, \gamma_s)^\top \)

\[
\Delta^{(i)}(\gamma) = \frac{y^\top V_\gamma^{-1} \left( \frac{1}{p_i} Z_i Z_i^\top \right) V_\gamma^{-1} y}{\text{trace} \left( V_\gamma^{-1} \frac{1}{p_i} Z_i Z_i^\top \right)} - \frac{y^\top V_\gamma^{-2} y}{\text{trace}(V_\gamma^{-1})} = 0, \quad 1 \leq i \leq s.
\]
Our second main result extends the model misspecification analysis to the linear model with feature groups in the sense that the true vector of SNRs $\gamma_0$ is asymptotically a root of the likelihood functions defined in (12). More concretely, we will show under certain conditions that $\Delta^{(i)}(\gamma_0) \xrightarrow{P} 0$ for $i = 1, \ldots, s$, where $\gamma_0$ consists of $\gamma_{0i} = \|\beta_i\|^2/\sigma_0^2$ for $i = 1, \ldots, s$. Unlike our misspecification analysis for the standard linear model (1), our result for the case of feature groups is not a standard MLE consistency result. We will discuss some ideas in Section 5 on how to derive a standard consistency result in future.

1.3 Organization of the Paper

This paper is organized as follows. In Section 2, we introduce our main results that characterize the conditions under which random effects MLE is consistent in estimating SNR and noise level for linear fixed effects models, either the standard case (1) or the case in which the design matrix is partitioned according to feature groups (8). In Section 3, we show extensive numerical simulation results of random effects model based MLE implemented on linear fixed effects models, and demonstrate the consistency of estimation that verifies our theoretical results. All proofs are deferred to Section 4. In Section 5, we will discuss several remaining problems that we plan to study in future.

2 Misspecification Analysis of Random Effects MLE

2.1 Main Results

In this section, we will introduce our main results on the asymptotic misspecification consistency analysis of random effects maximum likelihood estimation under the standard linear model (1) and the linear model with feature groups (8), respectively. We first state our result on the misspecification analysis for the likelihood equation (5):

**Theorem 2.1.** Consider the linear fixed effects model (1), where $Z$ is an $n \times p$ design matrix whose entries are independent, symmetric, sub-Gaussian, and variance-one random variables, and their maximum sub-Gaussian norm is uniformly upper bounded by some numerical constant $C_0$. Let $\beta$ be the vector of regression coefficients, and let $\epsilon$ be the vector of independent noise with mean zero and variance $\sigma_0^2$. Denote by $\gamma_0 := \|\beta\|^2/\sigma_0^2$ the true SNR value. Consider the asymptotic setting $n, p \to \infty$ such that $n/p \to \tau$ where $\tau > 0$. Also, assume that $\sigma_0^2 > 0$ and $\gamma_0 > 0$ are fixed constants for all $n$. Then there is a sequence of maximum likelihood estimates as solutions to (5) satisfying $\hat{\gamma}_n \to \gamma_0$ in probability. Moreover, the corresponding sequence of noise variance estimate in (7) satisfies $\hat{\sigma}_\epsilon^2 \to \sigma_0^2$ in probability.

**Remark 1.** This result is concerning the asymptotic consistency of random effects MLE of the noise variance and SNR under standard linear fixed effects models. We would like to highlight the following points:

- The asymptotic setting includes both the high-dimensional and moderate-dimensional cases since we only assume $n/p \to \tau > 0$. Also, no particular upper bound conditions have been imposed on $\|\beta\|_\infty$. 

• The assumption of independent entries in the design matrix is common in the literature of SNR or noise level estimation for linear models, e.g., Dicker (2014); Jiang et al. (2016); Janson et al. (2017); Dicker and Erdogdu (2016, 2017). The assumption that the sub-Gaussian entries are required to be symmetric is for technical reasons. See Section 2.3 for more details on the trick of Rademacher sequences. However, our experiments shown in Section 3 seem to indicate that this assumption is possibly unnecessary. We are interested in relaxing it in future work.

• A prominent result given in Jiang et al. (2016) is that when the true model is a sparse random effects one, they did not only show the consistency of non-sparse random effects MLE under model misspecification, but also established its asymptotic normality with explicit variance formula. Extending this result to our setting is beyond the scope of this work, but we are interested in doing so in future.

Our next result is regarding the misspecification analysis of random effects MLE for the linear fixed effects models with feature groups. To be concrete, we are going to show that the likelihood equations defined in (12) hold asymptotically at the vector of true group SNRs $\gamma_0$:

**Theorem 2.2.** Consider the linear fixed effects model with feature groups (8), where $Z = [Z_1, Z_2, \cdots, Z_s]$ is an $n \times (p_1 + p_2 + \cdots + p_s)$ design matrix whose entries are independent, symmetric, sub-Gaussian, and variance-one random variables, and their maximum sub-Gaussian norm is uniformly upper bounded by some numerical constant $C_0$. Let $\beta = [\beta_1^T, \ldots, \beta_s^T]^T$ be the $(p_1 + \cdots + p_s) \times 1$ vector of regression parameters, and let $\epsilon$ be the $n \times 1$ vector of independent noise with mean zero and variance $\sigma_0^2$. For $i = 1, \ldots, s$, denote the $i$-th group SNR as $\gamma_{0i} := \|\beta_i\|_2^2 / \sigma_0^2$ for $i = 1, \ldots, s$.

Consider the asymptotic setting $n, p_1, p_2, \cdots, p_s \to \infty$ such that $n/p_i \to \tau_i > 0$ for $i = 1, \ldots, s$. Also, assume that $\sigma_0^2 > 0$ and $\gamma_{01}, \ldots, \gamma_{0s} > 0$ are fixed constants for all $n$. Then the likelihood functions of the group SNRs defined in (12) satisfy $\Delta^{(i)}(\gamma_0) \to 0$, for $i = 1, \ldots, s$.

### 2.2 Comparison to Existing Works

As aforementioned, Theorem 2.1 follows the line of research in model misspecification analysis for random effects MLE. One prominent work in this line is Jiang et al. (2016), in which the true model is assumed to be a linear sparse random effects model. Both asymptotic analysis and normality have been discussed under such model misspecification. Our analysis follows their analytical framework, but new technical treatments are needed since we have not imposed any particular upper bound on $\|\beta\|_\infty$. Similar misspecification analysis when the ground truth has sparse or correlated random effects has also been conducted in Dicker and Erdogdu (2017) by using a uniform Hanson-Wright inequality.

In terms of the problem setting, Dicker and Erdogdu (2016) is similar to the present work since the fixed effects model is assumed to be the ground truth. The major difference between their work and ours is on the distribution of the design matrices: they assume that the entries of the design matrix are i.i.d. Gaussian, so that rotational invariance can reduce the true model into a correlated random effects model, for which the misspecification analysis is conducted in Dicker and Erdogdu (2017).
To the best of our knowledge, Theorem 2.2 is the first one in the literature for the model misspecification consistency analysis for linear random effects models with feature groups.

### 2.3 Outline of the Proof

We first give an overview of the proof of Theorem 2.1 for the standard linear model (1). Again, the framework follows that of Jiang et al. (2016) but detailed calculations are different. To start, denote $Z = [z_1, \ldots, z_p]$ in the form of concatenation of column vectors. By the assumption that the entries of $Z$ are independent and symmetric, we can replace $z_k$ with $z_k \xi_k$, where $\xi_k$’s are i.i.d. Rademacher random variables that are also independent with $z_1, \ldots, z_p$. Note that here $z_1, \ldots, z_p$ have the same distribution as before, and we still denote $Z = [z_1, \ldots, z_p]$. Also note that in this new representation, the design matrix becomes $\tilde{Z} = [z_1 \xi_1, \ldots, z_p \xi_p]$ rather than $Z$. In other words, the linear model (1) becomes

$$y = \tilde{Z} \beta + \varepsilon = \left( \sum_{k=1}^{p} \beta_k \xi_k z_k \right) + \varepsilon.$$  \hspace{1cm} (13)

Here we have $\tilde{Z} \tilde{Z}^\top = ZZ^\top$, so the formulas of $B_{\gamma}$ and $V_{\gamma}$ are the same as (6) and (3), respectively. Then, the score function on $\gamma$ is still defined as $\Delta(\gamma) = 0$ as in (5).

The crux of the proof is to derive the asymptotic limit of $\Delta(\gamma)$ for any fixed $\gamma > 0$. Note that under the new representation of the linear model (13), the randomness in $\Delta(\gamma)$ is due to $Z$, $\xi$ and $\varepsilon$. If we take the expectation of $\Delta(\gamma)$ over $\xi$ and $\varepsilon$ while conditioning on $Z$, we have

$$\begin{align*}
\mathbb{E}[y^\top V_\gamma^{-1} y | Z] &= \sum_{k=1}^{p} \beta_k^2 (z_k^\top V_\gamma^{-1} z_k) + \sigma_0^2 \text{trace}(V_\gamma^{-1}) \\
\mathbb{E}[y^\top V_\gamma^{-2} y | Z] &= \sum_{k=1}^{p} \beta_k^2 (z_k^\top V_\gamma^{-2} z_k) + \sigma_0^2 \text{trace}(V_\gamma^{-2}).
\end{align*}$$

As a result, we have the following formula of the conditional expectation of $\Delta(\gamma)$

$$\Delta_*(\gamma) := \mathbb{E}[\Delta(\gamma) | Z] = \frac{1}{\text{trace}(I_n - V_\gamma^{-1})} \left( \sum_{k=1}^{p} \beta_k^2 (z_k^\top V_\gamma^{-1} z_k) + \sigma_0^2 \text{trace}(V_\gamma^{-1}) \right) - \frac{n}{\text{trace}(I_n - V_\gamma^{-1}) \text{trace}(V_\gamma^{-1})} \left( \sum_{k=1}^{p} \beta_k^2 (z_k^\top V_\gamma^{-2} z_k) + \sigma_0^2 \text{trace}(V_\gamma^{-2}) \right).$$  \hspace{1cm} (14)

It is needed to show that $\Delta(\gamma) \approx \Delta_*(\gamma)$. The concentration of $\Delta(\gamma)$ relies on the concentrations of $y^\top V_\gamma^{-1} y$ and $y^\top V_\gamma^{-2} y$. Taking a major component of $y^\top V_\gamma^{-1} y$ for example:

$$A_1 := \left( \sum_{k=1}^{p} \beta_k \xi_k z_k \right)^\top V_\gamma^{-1} \left( \sum_{k=1}^{p} \beta_k \xi_k z_k \right),$$

in order to apply Chebyshev’s inequality to derive the concentration, the conditional variance of $A_1$ is given by

$$\text{Var}[A_1 | Z] = 2 \sum_{k \neq j} \beta_k^2 \beta_j^2 (z_k^\top V_\gamma^{-1} z_j)^2.$$
By applying the Sherman-Morrison-Woodbury formula as well as the Hoeffding’s inequality, we have the following approximations:

\[ \max_{k \neq j} |z_k^T V_\gamma^{-1} z_j|^2 \] can be well-controlled. These techniques play essential roles in controlling the conditional variances of \( y^T V_\gamma^{-1} y \) and \( y^T V_\gamma^{-2} y \).

Direct derivation of the asymptotic limit of \( \Delta_*(\gamma) \) is still not straightforward, since it involves the summation of \( p \) terms, where \( p \) grows proportionally with \( n \). Similar to the argument in Jiang et al. (2016), by applying the Sherman-Morrison-Woodbury formula as well as the Hanson-Wright inequality, we have the approximation \( z_k^T V_\gamma^{-1} z_k \approx (1 + \frac{\gamma}{p} \text{trace}(V_\gamma^{-1}))^{-1} \text{trace}(V_\gamma^{-1}) \) which is independent of the index \( k \), and thereby implies certain homogeneity of \( z_k^T V_\gamma^{-1} z_k \) across different \( k \). The same idea also applies to \( z_k^T V_\gamma^{-2} z_k \). Then, we have the following approximations:

\[
\begin{align*}
&\sum_{k=1}^p \beta_k^2 (z_k^T V_\gamma^{-1} z_k) \approx \frac{||\beta||^2}{p} \text{trace}(V_\gamma^{-1} ZZ^T), \\
&\sum_{k=1}^p \beta_k^2 (z_k^T V_\gamma^{-2} z_k) \approx \frac{||\beta||^2}{p} \text{trace}(V_\gamma^{-2} ZZ^T).
\end{align*}
\]

With the above approximations, noticing \( ||\beta||^2/\sigma_0^2 = \gamma_0 \), we can find the following surrogate of \( \Delta_*(\gamma) \):

\[
\Delta_{**}(\gamma) = \frac{\sigma_0^2}{\text{trace}(I_n - V_\gamma^{-1})} \left( \frac{\text{trace}\left(V_\gamma^{-1}\left(I_n + \frac{\gamma_0}{p} ZZ^T\right)\right)}{\text{trace}(I_n - V_\gamma^{-1})} \right) - \frac{n\sigma_0^2}{\text{trace}(I_n - V_\gamma^{-1})} \left( \frac{\text{trace}\left(V_\gamma^{-2}\left(I_n + \frac{\gamma_0}{p} ZZ^T\right)\right)}{\text{trace}(V_\gamma^{-1})} \right).
\]

It turns out that the asymptotic limit of \( \Delta_{**}(\gamma) \) is easy to obtain by the well-known Marčenko-Pastur law from random matrix theory. Specifically, we can show that \( \Delta_{**}(\gamma) \xrightarrow{a.s.} c_\gamma > 0 \) for any fixed \( \gamma > \gamma_0 \), \( \Delta_{**}(\gamma) \xrightarrow{a.s.} c_\gamma < 0 \) for any fixed \( \gamma < \gamma_0 \) and \( \Delta_{**}(\gamma_0) = 0 \). This implies that \( \Delta(\gamma) \xrightarrow{P} c_\gamma > 0 \) for any fixed \( \gamma > \gamma_0 \), \( \Delta(\gamma) \xrightarrow{P} c_\gamma < 0 \) for any fixed \( \gamma < \gamma_0 \) and \( \Delta(\gamma_0) = 0 \).

Finally, we can show that there is a sequence of roots \( \hat{\gamma}_n \) of \( \Delta(\gamma) \), such that \( \hat{\gamma}_n \xrightarrow{P} \gamma_0 \). This can be achieved by standard arguments in consistency analysis of MLE, see, e.g., Theorem 3.7 of Lehmann and Casella (2006).

The proof of Theorem 2.2 is technically more involved but has a similar roadmap. In particular, for \( i = 1, \ldots, s \), we define

\[
\Delta_{**}(\gamma) = \sigma_0^2 \left( 1 - \frac{\gamma_0}{\gamma_i} \right) \left( \frac{\text{trace}\left(V_\gamma^{-2}\frac{1}{p_i} Z_i Z_i^T\right)}{\text{trace}(V_\gamma^{-1}\frac{1}{p_i} Z_i Z_i^T)} - \frac{\text{trace}(V_\gamma^{-2})}{\text{trace}(V_\gamma^{-1})} \right)
\]

\[
+ \sigma_0^2 \sum_{r \neq i} r_{\gamma r} \left( \frac{\gamma_{0 r}}{\gamma_{r}} - \frac{\gamma_{0 i}}{\gamma_{i}} \right) \left( \frac{\text{trace}\left(V_\gamma^{-1}\frac{1}{p_i} z_i z_i^T V_\gamma^{-1}\frac{1}{p_r} z_r z_r^T\right)}{\text{trace}(V_\gamma^{-1}\frac{1}{p_i} z_i z_i^T)} - \frac{\text{trace}(V_\gamma^{-2}\frac{1}{p_r} z_r z_r^T)}{\text{trace}(V_\gamma^{-1})} \right).
\]

It is obvious that \( \Delta_{**}(\gamma_0) = 0 \). Then, it suffices to show \( \Delta_{**}(\gamma_0) - \Delta_{**}(\gamma_0) \xrightarrow{P} 0 \). Again, we can introduce \( \Delta_{**}(\gamma_0) \), which is the mean of \( \Delta(\gamma) \) conditional on \( Z \), as an intermediate step to establish \( \Delta_{**}(\gamma_0) \approx \Delta_{**}(\gamma_0) \).
3  Experiments

Empirical behavior of maximum likelihood estimation for random effects models has been extensively studied in the literature, see e.g., Jiang et al. (2016). Also see Dicker and Erdogdu (2016) for numerical comparisons between random effects MLE and other approaches including method of moments (Dicker, 2014) and EigenPrism (Janson et al., 2017). Therefore, we here don’t make comparisons between random effects model based MLE with other methods in estimating SNRs and noise levels. Instead, the objective of our numerical simulations is to study empirically how the consistency of random effects MLE relies on some key parameters under model misspecification, including the magnitude decaying rate of the regression coefficients, the ratio \( \tau = n/p \), and the true SNR \( \gamma_0 = \| \beta \|^2 / \sigma_0^2 \). Similar empirical study will also be implemented to linear models with feature groups (8).

3.1 Standard Linear Models

We first consider the standard linear model (1). In particular, we consider maximizing the log-likelihood function (2) by the Minorization-Maximization (MM) Algorithm, which has been proposed and studied in (Zhou et al., 2019). For completeness, we give a summary of this method in Algorithm 1.

---

**Algorithm 1**  MM algorithm of random effects MLE for the fixed effects model (1).

**Input:**  The design matrix \( Z \) and the vector of responses \( y \);

**Output:**  Maximum likelihood estimates \( \hat{\gamma} \) and \( \hat{\sigma}_\varepsilon^2 \)

1:  Simultaneous congruence decomposition: \((D, U) \leftarrow (p^{-1}ZZ^\top, I_n)\);

2:  Transform data: \( \tilde{y} \leftarrow U^\top y \);

3:  Initialize \( \sigma_{0,(0)}, \sigma_{1,(0)} > 0 \);

4:  repeat

5:  \[
\sigma_{0,(t+1)}^2 \leftarrow \sigma_{0,(t)}^2 \frac{\tilde{y}^\top (\sigma_{0,(t)}^2 D + \sigma_{1,(t)}^2 I)^{-1} D (\sigma_{0,(t)}^2 D + \sigma_{1,(t)}^2 I)^{-1} \tilde{y}}{\text{tr}[(\sigma_{0,(t)}^2 D + \sigma_{1,(t)}^2 I)^{-1} D]}
\]

6:  \[
\sigma_{1,(t+1)}^2 \leftarrow \sigma_{2,(t)}^2 \frac{\tilde{y}^\top (\sigma_{0,(t)}^2 D + \sigma_{1,2(t+1)} I)^{-2} \tilde{y}}{\text{tr}[(\sigma_{0,(t)}^2 D + \sigma_{1,(t)}^2 I)^{-1} D]}
\]

7:  until the log-likelihood function

\[
| l(\sigma_{0,(t+1)}^2, \sigma_{1,(t+1)}^2) - l(\sigma_{0,(t)}^2, \sigma_{1,(t)}^2) | < 1e - 4
\]

8:  Set the final maximum likelihood estimates as

\[
\hat{\sigma}_\varepsilon^2 \leftarrow \sigma_{1,(t)}^2, \quad \hat{\gamma} \leftarrow \sigma_{0,(t)}^2 / \sigma_{1,(t)}^2, \quad i = 1, \ldots, s.
\]

---

As aforementioned, the purpose of our numerical experiments is to study how the performance of random effects model based MLE relies on key parameters of the linear model.
Throughout our experiments, we generate i.i.d. $\mathcal{N}(0, \sigma_0^2)$ noise with $\sigma_0^2 = 0.5$. In addition, the vector of regression coefficients $\beta$ is generated in the form of

$$\beta = p^{-1/2}a \left(1, 2^{-g}, 3^{-g}, \ldots, p^{-g}\right)^\top.$$  \hfill (16)

Here $g \geq 0$ determines the rate of decay for the coefficients. The parameter $a > 0$ is usually determined by given values of $g$ and the SNR $\gamma_0$ (the noise level $\sigma_0^2 = 1/2$ is fixed), and thus usually not fixed even in the same simulation setting.

Now we consider the following three simulation settings to study the performance of random effects MLE:

(i) (Varying magnitude decay): Fix $n = 1200$, $p = 2000$, $\gamma_0 = 2$. Let $g$ be varied from 0 to 2.

(ii) (Varying dimension): Fix $n = 1200$, $g = 0.5$, $\gamma_0 = 2$. Let $1/\tau = p/n$ be varied from $2/3$ to 3.

(iii) (Varying sample size): Fix $p = 2100$, $g = 0.5$, $\gamma_0 = 2$. Let $\tau = n/p$ be varied from $1/3$ to $2/3$.

(iv) (Varying SNR): Fix $n = 1200$, $p = 2000$, $g = 0.5$. Let $\gamma_0$ be varied from 0.5 to 5.

Two configurations of the design matrix $Z$ are considered: i.i.d. $\mathcal{N}(0, 1)$ entries and i.i.d. Rademacher entries. It is clear that in both cases the entries have zero mean and unit variance. For each simulation, Algorithm 1 is implemented over 100 independent datasets.

The performances of random effects MLE for $\gamma_0$ and $\sigma_0^2$ under simulation settings (i)(ii)(iii)(iv) are shown in Figure 1 for Gaussian designs and in Figure 2 for Rademacher designs. As predicted by Theorem 2.1, the random effects MLE appears to be consistent.
in estimating both the SNR and noise variance. From Figure 1 (b)(c)(f)(g) and Figure 2 (b)(c)(f)(g), we can conclude that the aspect ration $1/\tau = p/n$ has significant impacts on the behaviors of the random effects MLE $\hat{\gamma}$ and $\hat{\sigma}^2$: larger sample size $n$ leads to smaller variances of the estimates. Furthermore, Figure 1(d) and Figure 2(d) indicate that larger true SNR $\gamma_0$ leads to larger variance of the SNR estimate $\hat{\gamma}$.

Moreover, following Jiang et al. (2016), we consider the case where the design $Z$ is generated according to the standardized genotype matrix. First, we simulate $f_i \sim \text{Uni}[0.05, 0.5], i = 1, \ldots, p$ as the allele frequencies for pSNPs, then the entries of the genotype matrix $U$ are generated from a discrete distribution which assigns the probabilities $(1 - f_j)^2, 2f_j(1 - f_j), f_j^2$ to $\{0, 1, 2\}$ respectively. At last, we standardize each column of $U$ to have zero mean and unit variance, then we denote the standardized matrix as $Z$. Here the entries of the design $Z$ are not symmetric random variables, which doesn’t satisfy our assumptions in Theorem 2.1. Results are shown in Figure 3, in which the random effects model based MLE still seems to be consistent.

### 3.2 Linear Models with Feature Groups

In this subsection, we consider estimating the noise variance, the group SNRs, and the total SNR for the linear model (8) when $s = 2$, which is

$$y = Z_1\beta_1 + Z_2\beta_2 + \varepsilon.$$  

The log-likelihood function is (9) and maximized by the Minorization-Maximization (MM) Algorithm (Zhou et al., 2019), which is summarized in Algorithm 2.
Figure 3: Estimates of SNR and noise level for simulations under the standardized genotype design. Parameter values: $n = 1200$, $p = 2000$, $g = 0.5$. The true SNR $\gamma_0$ and $\sigma_0^2$ are marked in dash line. The black diamonds represent average estimates $\hat{\gamma}$ and $\hat{\sigma}^2$.

Algorithm 2 MM algorithm for the random effects MLE of the fixed effects model (8).

**Input:** The design matrix $Z_i (i = 1, \ldots, s)$ and the vector of responses $y$;

**Output:** Maximum likelihood estimates $\hat{\gamma}_1, \ldots, \hat{\gamma}_s$ and $\hat{\sigma}^2$.

1. Initialize $\sigma_i^{(0)} > 0, i = 0, 1, \ldots, s$;
2. repeat
3. $\Omega(t) \leftarrow \sigma_{0,t}^2 + \sum_{i=1}^{s} (\sigma_{i,t}^2/p_i) Z_i Z_i^\top$;
4. $\sigma_{0,t+1}^2 \leftarrow \sigma_{0,t}^2 \frac{y^\top \Omega_{(t)}^{-2} y}{\text{trace} (\Omega_{(t)}^{-1})}$;
5. $\sigma_{i,t+1}^2 \leftarrow \sigma_{i,t}^2 \sqrt{\frac{y^\top \Omega_{(t)}^{-1} p_i^{-1} Z_i Z_i^\top \Omega_{(t)}^{-1} y}{\text{trace} (\Omega_{(t)}^{-1} p_i^{-1} Z_i Z_i^\top)}}$, $i = 1, \ldots, s$;
6. until the log-likelihood function satisfies
$$\left| l(\sigma_0^{(t+1)}, \sigma_1^{(t+1)}, \ldots, \sigma_s^{(t+1)}) - l(\sigma_0^{(t)}, \sigma_1^{(t)}, \ldots, \sigma_s^{(t)}) \right| < 10^{-4};$$
7. Set the final maximum likelihood estimates as
$$\hat{\sigma}_i^2 \leftarrow \sigma_{0,t}^2, \quad \hat{\gamma}_i \leftarrow \frac{\sigma_{i,t}^2}{\sigma_{0,t}^2}, \quad i = 1, \ldots, s.$$

We study how the performance of MLE for linear random effects models with feature groups depends on the balancedness between $Z_1$ and $Z_2$. In this simulation, we generate noise from $\mathcal{N}(0, \sigma_0^2)$ with $\sigma_0^2 = 0.5$ and $\beta_1$ and $\beta_2$ from the equality (16) by simply replacing
$p$ with $p_1$ and $p_2$, that is,

\[ \beta_1 = p_1^{-1/2} a_1 \left( 1, 2^{-g_1}, 3^{-g_1}, \cdots, p_1^{-g_1} \right)^\top, \]
\[ \beta_2 = p_2^{-1/2} a_2 \left( 1, 2^{-g_2}, 3^{-g_2}, \cdots, p_2^{-g_2} \right)^\top, \]

where the parameters $a_1, a_2 > 0$ are determined by given values of $g_1, g_2$ and the partitioned SNR $\gamma_{01}, \gamma_{02}$. The design matrices $Z_1$ and $Z_2$ are simulated with i.i.d. Rademacher elements.

Then we fix $n = 1000$, $g_1 = g_2 = 0.5$, $\gamma_{01} = \gamma_{02} = 2$, $p_1 + p_2 = 2100$. Without loss of generality, we can assume $p_1 > p_2$. Varying the ratio $p_1/p_2$ from 1 to 5, the results are shown in Figure 4. This suggests that under the unbalanced case, the MLE still gives nearly unbiased estimate of the partitioned SNR $\gamma_{01}, \gamma_{02}$ and the total SNR $\gamma$, which is consistent with the implication by Theorem 2.2.

![Figure 4: Estimates of the SNR $\gamma_1, \gamma_2, \gamma = \gamma_1 + \gamma_2$ and noise variance $\sigma^2$ from 100 independent datasets. Structured $Z_1$ and $Z_2$ simulated from i.i.d. Rademacher distribution. The true SNR $\gamma_{01}, \gamma_{02}, \gamma$ and $\sigma^0_2$ are marked in dash line and the black diamonds represent the averages.](image)

### 4 Proofs

#### 4.1 Preliminaries

**Theorem 4.1** (Marčenko-Pastur law, V. A. Marchenko (1967)). Let $Z$ be an $n \times p$ random matrix whose entries are i.i.d. random variables with mean 0 and variance 1 in which $n/p \to \tau \in (0, \infty)$ as $n, p \to \infty$. Then the empirical spectral distribution (ESD) of $S = p^{-1}ZZ^\top$, which is defined as $F_S$, converges almost surely (a.s.) in distribution to $F_\tau$, whose p.d.f. is given by

\[
    f_\tau(x) = \begin{cases} 
        \frac{1}{2\pi \tau x} \sqrt{(b_+(\tau) - x)(x - b_-(\tau))} & b_-(\tau) \leq x \leq b_+(\tau) \\
        0 & \text{elsewhere} 
    \end{cases}
\]

and a point mass $1 - 1/\tau$ at the origin if $\tau > 1$, where $b_\pm(\tau) = (1 \pm \sqrt{\tau})^2$. 

13
Theorem 4.2 (Bai (1999), Theorem 2.8). Let $Z$ be an $n \times p$ random matrix whose entries are independent random variables with mean 0 and variance 1. Assume that $n/p \to \tau \in (0, \infty)$ and that for any $\delta > 0$,

$$\frac{1}{\delta^2 np} \sum_{i,j} \mathbb{E} \left[ |z_{ij}^{(n)}|^2 I(|z_{ij}^{(n)}| \geq \delta \sqrt{n}) \right] \to 0.$$  

Then $F^S$ tends almost surely to the Marchenko-Pastur law with ratio index $\tau$.

Corollary 4.1. Under the assumption of Theorem 4.1, for any integer $l$, we have

$$\frac{1}{n} \text{trace}(S^l) \xrightarrow{a.s.} \int_{b_-(\tau)}^{b_+(\tau)} x^l f_\tau(x) \, dx \quad \text{as} \quad n, p \to \infty.$$  

Define the sub-Gaussian norm of a random variable $\zeta$ as

$$\|\zeta\|_{\psi_2} \equiv \sup_{q \geq 1} \left\{ q^{-1/2} \mathbb{E} |\zeta|^q \right\}^{1/q}.$$  

A random variable $\zeta$ is sub-Gaussian if and only if its sub-Gaussian norm $\|\zeta\|_{\psi_2} < \infty$. We have the following equivalent characterizations on the sub-Gaussianity of a random variable:

Lemma 4.1 (Vershynin (2010), Lemma 5.5). A random variable $\zeta$ is sub-Gaussian if and only if

1) $\|\zeta\|_{\psi_2} < \infty$;

2) $\mathbb{P}\{|\zeta| > t\} \leq \exp(1 - t^2/K^2)$ for some parameter $K > 0$ and all $t > 0$.

Part 2) actually implies that the design matrix under the setting of Theorem 2.1, in which the entries have sub-Gaussian norms that are uniformly upper bounded, satisfies the conditions in Theorem 4.2. In fact, if $\zeta$ is sub-Gaussian random variable, then by the identity $\mathbb{E}[X] = \int_0^\infty \mathbb{P}(X > t) \, dt$ for any nonnegative random variable $X$, we have

$$\mathbb{E} \left[ |\zeta|^2 I(|\zeta| \geq \delta \sqrt{n}) \right] = \int_{\delta \sqrt{n}}^{\infty} \mathbb{P}\{|\zeta| > t\} 2t \, dt + \delta^2 n \mathbb{P}\{|\zeta| > \delta \sqrt{n}\} \leq 2 \int_{\delta \sqrt{n}}^{\infty} e^{1-t^2/K^2} \, dt + \delta^2 ne^{1-\delta^2 n/K^2} = (K^2 + \delta^2 n)e^{1-\delta^2 n/K^2}.$$  

This implies that for $n \times p$ random matrices $Z$ whose entries have uniformly upper bounded sub-Gaussian norms,

$$\frac{1}{\delta^2 np} \sum_{i,j} \mathbb{E} \left[ |z_{ij}^{(n)}|^2 I(|z_{ij}^{(n)}| \geq \delta \sqrt{n}) \right] \to 0,$$  

as $n, p \to \infty$, for any $\delta > 0$.  

14
Proposition 4.3 (Hanson–Wright inequality, Rudelson and Vershynin (2013)). Let \( \zeta = (\zeta_1, \ldots, \zeta_n)^T \), where the \( \zeta_i \)'s are independent random variables satisfying \( \mathbb{E}(\zeta_i) = 0 \) and \( \|\zeta_i\|_{\psi_2} \leq K < \infty \). Let \( A \) be an \( n \times n \) deterministic matrix. Then we have for any \( t > 0 \),
\[
\mathbb{P}\{|\zeta^T A \zeta - \mathbb{E}(\zeta^T A \zeta)| > t\} \leq 2 \exp\left\{-c \min\left( \frac{t^2}{K^4 \|A\|^2_F}, \frac{t}{K^2 \|A\|} \right) \right\},
\]
where \( c > 0 \) is an absolute constant. Here \( \|A\| \) and \( \|A\|_F \) denote the operator and Frobenius norms of \( A \), respectively.

Proposition 4.4 (Hoeffding-type inequality, Vershynin (2010), Proposition 5.10). Let \( \zeta = (\zeta_1, \ldots, \zeta_n)^T \), where the \( \zeta_i \)'s are independent centered sub-Gaussian random variables. Let \( K = \max_{1 \leq i \leq n} \|\zeta_i\|_{\psi_2} \) and \( \mathbf{a} = (a_1, \ldots, a_N)^T \in \mathbb{R}^N \). Then we have for any \( t \geq 0 \),
\[
\mathbb{P}\{|a^T \zeta| > t\} \leq \exp\left\{-c \frac{t^2}{K^2 \|a\|_2^2} \right\},
\]
where \( c > 0 \) is an absolute constant.

Proposition 4.5 (Bernstein-type inequality, Vershynin (2010), Proposition 5.16). Let \( \zeta = (\zeta_1, \ldots, \zeta_n)^T \), where the \( \zeta_i \)'s are independent centered sub-Gaussian random variables. Let \( K = \max_{1 \leq i \leq n} \|\zeta_i\|_{\psi_2} \) and \( \mathbf{a} = (a_1, \ldots, a_N)^T \in \mathbb{R}^N \). Then we have for any \( t \geq 0 \),
\[
\mathbb{P}\{|a^T \zeta| > t\} \leq 2 \exp\left\{-c \min\left( \frac{t^2}{K^2 \|a\|^2_2}, \frac{t}{K \|a\|_\infty} \right) \right\},
\]
where \( c > 0 \) is an absolute constant.

Theorem 4.6 (Sherman-Morrison-Woodbury formula, Horn and Johnson (1990), Page 19). Let \( P \) and \( Q \) be \( n \)-dimensional non-singular matrices such that \( Q = P + UV^T \), where \( U, V \in \mathbb{R}^{n \times q} \). Then
\[
Q^{-1} = (P + UV^T)^{-1} = P^{-1} - P^{-1}U(I_q + V^TP^{-1}U)^{-1}V^TP^{-1}.
\]

4.2 Proof of Theorem 2.1

As aforementioned, we basically follow the proof framework used in Jiang et al. (2016), which studies the model misspecification of random effects MLE when the true model is a sparse random effects model. However, since we are studying the general fixed effects model, in which \( \beta \) is allowed to be spiky or very sparse (we don’t have particular upper bounds on \( \|\beta\|_\infty \)), new technical treatments are needed, particularly for controlling \( \Delta(\gamma) - \Delta_*(\gamma) \).

For completeness, also as a warm-up of the proof of Theorem 2.2, we give a self-contained proof of Theorem 2.1 in this subsection.

By the fact that \( \frac{1}{p} \mathbb{Z} \mathbb{Z}^T = \frac{1}{\gamma} (V_\gamma - I_n) \), plugged to (6), we get
\[
B_\gamma = \frac{V_\gamma^{-1} - V_\gamma^{-2}}{\text{trace}(I_n - V_\gamma^{-1})} - \frac{V_\gamma^{-2}}{\text{trace}(V_\gamma^{-1})}
\]
\[
= \frac{1}{\text{trace}(I_n - V_\gamma^{-1})} V_\gamma^{-1} - \frac{n}{\text{trace}(I_n - V_\gamma^{-1}) \text{trace}(V_\gamma^{-1})} V_\gamma^{-2}.
\]
Then the likelihood function of the SNR parameter $\gamma$ is

$$\Delta(\gamma) = y^\top B_\gamma y = \frac{y^\top V_\gamma^{-1}y}{\text{trace}(I_n - V_\gamma^{-1})} - \frac{ny^\top V_\gamma^{-2}y}{\text{trace}(I_n - V_\gamma^{-1}) \text{trace}(V_\gamma^{-1})}.$$  

In the following, we will discuss how to calculate $y^\top V_\gamma^{-1}y$ and $y^\top V_\gamma^{-2}y$. In fact

$$y^\top V_\gamma^{-1}y = \left( \left( \sum_{k=1}^{p} \beta_k \xi_k z_k \right) + \varepsilon \right)^\top V_\gamma^{-1} \left( \left( \sum_{k=1}^{p} \beta_k \xi_k z_k \right) + \varepsilon \right)$$

$$\begin{align*}
&= \left( \sum_{k=1}^{p} \beta_k \xi_k z_k \right)^\top V_\gamma^{-1} \left( \sum_{k=1}^{p} \beta_k \xi_k z_k \right) + 2 \left( \sum_{k=1}^{p} \beta_k \xi_k z_k \right)^\top V_\gamma^{-1} \varepsilon + \varepsilon^\top V_\gamma^{-1} \varepsilon, \\
&\quad \text{(17)}
\end{align*}$$

and similarly,

$$y^\top V_\gamma^{-2}y = \left( \left( \sum_{k=1}^{p} \beta_k \xi_k z_k \right) + \varepsilon \right)^\top V_\gamma^{-2} \left( \left( \sum_{k=1}^{p} \beta_k \xi_k z_k \right) + \varepsilon \right)$$

$$\begin{align*}
&= \left( \sum_{k=1}^{p} \beta_k \xi_k z_k \right)^\top V_\gamma^{-2} \left( \sum_{k=1}^{p} \beta_k \xi_k z_k \right) + 2 \left( \sum_{k=1}^{p} \beta_k \xi_k z_k \right)^\top V_\gamma^{-2} \varepsilon + \varepsilon^\top V_\gamma^{-2} \varepsilon. \\
&\quad \text{(18)}
\end{align*}$$

Recall that we have defined $\Delta_*(\gamma) := \mathbb{E}[\Delta(\gamma)\mathbf{|} \mathbf{Z}]$ in (14) and $\Delta_*(\gamma)$ in (15). In the following, we will follow the proof roadmap given in Section 2.3 to establish the consistency of $\hat{\gamma}$.

### 4.2.1 Control of $\Delta(\gamma) - \Delta_*(\gamma)$

Theorem 4.2 implies

$$\frac{1}{n} \text{trace} (V_\gamma^{-1}) = \frac{1}{n} \sum_{k=1}^{n} \frac{1}{1 + \gamma \lambda_k} \frac{a_k}{c_{a_k}^*} \begin{cases} f_{b_k^+(\tau)}(1 + \gamma x)^{-1} f_r(x)dx & \text{if } \tau \leq 1 \\ f_{b_k^+(\tau)}(1 + \gamma x)^{-1} f_r(x)dx + 1 - \frac{1}{\tau} & \text{if } \tau > 1. \end{cases}$$

Also, $\frac{1}{n} \text{trace} (I_n - V_\gamma^{-1}) = 1 - \frac{1}{n} \text{trace} (V_\gamma^{-1})$. Thus to show $\Delta(\gamma) - \Delta_*(\gamma) \xrightarrow{P} 0$, we need to control

$$y^\top V_\gamma^{-1}y - \mathbb{E}[y^\top V_\gamma^{-1}y\mathbf{|} \mathbf{Z}], \text{ and } y^\top V_\gamma^{-2}y - \mathbb{E}[y^\top V_\gamma^{-2}y\mathbf{|} \mathbf{Z}].$$

By (17) and (18), it is sufficient to control

$$A_i - \mathbb{E}[A_i\mathbf{|} \mathbf{Z}], B_i - \mathbb{E}[B_i\mathbf{|} \mathbf{Z}], \text{ and } C_i - \mathbb{E}[C_i\mathbf{|} \mathbf{Z}], \quad i = 1, 2.$$

Take $A_1$ as an example, first we control $\text{Var}[A_1\mathbf{|} \mathbf{Z}] = \mathbb{E}[A_1^2\mathbf{|} \mathbf{Z}] - [\mathbb{E}[A_1\mathbf{|} \mathbf{Z}]]^2$ and then give a control of $A_1 - \mathbb{E}[A_1\mathbf{|} \mathbf{Z}]$ by Chebyshev’s inequality.
Let’s start by calculating \( \text{Var}[A_1|Z] \). We have

\[
A_1^2 = \sum_{k=1}^{p} \sum_{j=1}^{p} \sum_{l=1}^{p} \sum_{m=1}^{p} \beta_k \beta_j \beta_l \beta_m \xi_k \xi_j \xi_l \xi_m (z_k^T V^{-1}_\gamma z_j)(z_l^T V^{-1}_\gamma z_m)
\]

\[
:= \sum_{k=1}^{p} \sum_{j=1}^{p} \sum_{l=1}^{p} \sum_{m=1}^{p} g_{k,j,l,m}.
\]

Notice that \( \xi_1, \ldots, \xi_p \) are independent Rademacher random variables. Therefore, if \((k, j, l, m)\) has an odd multiplicity, we have \( \mathbb{E}[\xi_k \xi_j \xi_l \xi_m] = 0 \). This implies that

\[
\mathbb{E}[A_1^2|Z] = \sum_{k=1}^{p} \mathbb{E}[g_{k,k,k,k}|Z] + \sum_{k \neq j} \mathbb{E}[g_{k,k,j,j}|Z] + \sum_{k \neq j} \mathbb{E}[g_{k,j,k,j}|Z] + \sum_{k \neq j} \mathbb{E}[g_{j,j,k,k}|Z]
\]

\[
= \sum_{k=1}^{p} \beta_k^4(z_k^T V^{-1}_\gamma z_k)^2 + \sum_{k \neq j} \beta_k^2 \beta_j^2(z_k^T V^{-1}_\gamma z_k)(z_j^T V^{-1}_\gamma z_j) + 2 \sum_{k \neq j} \beta_k^2 \beta_j^2(z_k^T V^{-1}_\gamma z_j)^2.
\]

Since \( \mathbb{E}[A_1|Z] = \sum_{k=1}^{p} \beta_k^2 (z_k^T V^{-1}_\gamma z_k) \), which implies that

\[
(\mathbb{E}[A_1|Z])^2 = \sum_{k=1}^{p} \beta_k^4(z_k^T V^{-1}_\gamma z_k)^2 + \sum_{k \neq j} \beta_k^2 \beta_j^2(z_k^T V^{-1}_\gamma z_k)(z_j^T V^{-1}_\gamma z_j).
\]

Then

\[
\text{Var}[A_1|Z] = \mathbb{E}[A_1^2|Z] - (\mathbb{E}[A_1|Z])^2 = 2 \sum_{k \neq j} \beta_k^2 \beta_j^2(z_k^T V^{-1}_\gamma z_j)^2.
\]

Similarly, we can have \( \mathbb{E}[A_2|Z] = \sum_{k=1}^{p} \beta_k^2 (z_k^T V^{-2}_\gamma z_k) \) and

\[
\text{Var}[A_2|Z] = 2 \sum_{k \neq j} \beta_k^2 \beta_j^2(z_k^T V^{-2}_\gamma z_j)^2.
\]

To deal with \( z_k^T V^{-1}_\gamma z_j \) and \( z_k^T V^{-2}_\gamma z_j \), we define

\[
V_{\gamma,-k} = I_n + \frac{1}{p} \sum_{l \neq k} z_l z_l^T
\]

(19)

where \( z_l \) is the \( l \)th column of \( Z \). Define

\[
\rho_k := z_k^T V^{-1}_{\gamma,-k} z_k, \quad \phi_k := z_k^T V^{-2}_{\gamma,-k} z_k, \quad \psi_k := z_k^T V^{-3}_{\gamma,-k} z_k.
\]

(20)

There is a simple relationship between \( \psi_k, \phi_k \) and \( \rho_k \): \( \psi_k \leq \phi_k \leq \rho_k \). Since \( I_n - V^{-1}_{\gamma,-k} \succeq 0 \), we know that

\[
\rho_k - \phi_k = z_k^T V^{-1/2}_{\gamma,-k} (I - V^{-1}_{\gamma,-k}) V^{-1/2}_{\gamma,-k} z_k \geq 0.
\]

i.e., \( \phi_k \leq \rho_k \).
We can similarly obtain $\psi_k \leq \phi_k$. Using Sherman-Morrison-Woodbury formula (Theorem 4.6), we have
\[
V_\gamma^{-1} = V_{\gamma,-k}^{-1} - \frac{\gamma}{p}(1 + \frac{\gamma}{p} \rho_k)^{-1} V_{\gamma,-k}^{-1} z_k z_k^\top V_{\gamma,-k}^{-1},
\] (21)
and
\[
V_\gamma^{-2} = \left(V_{\gamma,-k}^{-1} - \frac{\gamma}{p}(1 + \frac{\gamma}{p} \rho_k)^{-1} V_{\gamma,-k}^{-1} z_k z_k^\top V_{\gamma,-k}^{-1}\right)^2 \\
= V_{\gamma,-k}^{-2} - \frac{\gamma}{p}(1 + \frac{\gamma}{p} \rho_k)^{-1} V_{\gamma,-k}^{-2} z_k z_k^\top V_{\gamma,-k}^{-1} - \frac{\gamma}{p}(1 + \frac{\gamma}{p} \rho_k)^{-1} V_{\gamma,-k}^{-1} z_k z_k^\top V_{\gamma,-k}^{-2} \\
+ \left(\frac{\gamma}{p}\right)^2 (1 + \frac{\gamma}{p} \rho_k)^{-2} \phi_k V_{\gamma,-k}^{-1} z_k z_k^\top V_{\gamma,-k}^{-1}. 
\] (22)
These equalities imply that
\[
(z_k^\top V_\gamma^{-1} z_j)^2 = (1 + \frac{\gamma}{p} \rho_k)^{-2} (z_k^\top V_{\gamma,-k}^{-1} z_j)^2 \leq (z_k^\top V_{\gamma,-k}^{-1} z_j)^2 
\] and
\[
(z_k^\top V_\gamma^{-2} z_j)^2 = \left((1 + \frac{\gamma}{p} \rho_k)^{-1} z_k^\top V_{\gamma,-k}^{-2} z_j + \left(-\frac{\gamma}{p} \phi_k (1 + \frac{\gamma}{p} \rho_k)^{-2} z_k^\top V_{\gamma,-k}^{-1} z_j\right)\right)^2 \\
\leq \frac{1}{2} (1 + \frac{\gamma}{p} \rho_k)^{-2} (z_k^\top V_{\gamma,-k}^{-2} z_j)^2 + \frac{1}{2} \left(\frac{\gamma}{p} \phi_k\right)^2 (1 + \frac{\gamma}{p} \rho_k)^{-4} (z_k^\top V_{\gamma,-k}^{-1} z_j)^2 \\
\leq 2 \left((z_k^\top V_{\gamma,-k}^{-2} z_j)^2 + (z_k^\top V_{\gamma,-k}^{-1} z_j)^2\right) 
\] (23)
where the last inequality is due to $0 < \phi_k \leq \rho_k$.

Denote $Z_{-k} = [z_1, \ldots, z_{k-1}, z_{k+1}, \ldots, z_j]$. Note that the components of $z_k$ are independent mean-zero sub-Gaussian random variables, conditional on $Z_{-k}$, by Proposition 4.4, we have, for any $k \neq j$ and $t \geq 0$,
\[
P \left\{ |z_k^\top V_{\gamma,-k}^{-1} z_j| \geq t \left| Z_{-k}\right.\right\} \leq e \exp \left\{-\frac{t^2}{K^2 \| V_{\gamma,-k}^{-1} z_j \|_2^2}\right\},
\]
where $c$ and $K$ are some positive constants. By letting $t = K \sqrt{\frac{3 \log p}{c} \| V_{\gamma,-k}^{-1} z_j \|_2}$, it follows
\[
P \left\{ |z_k^\top V_{\gamma,-k}^{-1} z_j| \geq C \sqrt{\log p \| V_{\gamma,-k}^{-1} z_j \|_2} \left| Z_{-k}\right.\right\} \leq \frac{e}{p^{3}},
\]
where $C$ is some positive constant. It further implies the unconditional probability inequality
\[
P \left\{ |z_k^\top V_{\gamma,-k}^{-1} z_j| \geq C \sqrt{\log p \| V_{\gamma,-k}^{-1} z_j \|} \right\} \leq \frac{e}{p^{3}}.
\] (24)
By the fact $\|\mathbf{V}_{\gamma, -k}^{-1}\| \leq 1$, we have $\|\mathbf{V}_{\gamma, -k}^{-1} \mathbf{z}_j\| \leq \|\mathbf{z}_j\|$. Note that $z_{1j}^2 - 1, z_{2j}^2 - 1, \ldots, z_{nj}^2 - 1$ are independent centered sub-exponential random variables, by the Proposition 4.5, we have

$$\mathbb{P} \left\{ \left| \sum_{i=1}^{n} (z_{ij}^2 - 1) \right| \geq t \right\} \leq 2 \exp \left\{ -c \min \left( \frac{t^2}{K^2 n}, \frac{t}{K} \right) \right\},$$

where $c$ and $K$ are some positive constants. Take $t = K \sqrt{3n \log p}$, then we get

$$\mathbb{P} \left\{ \|\mathbf{z}_j\|^2 - n \geq C \sqrt{n \log p} \right\} \leq \frac{2}{p^3}.$$

Combining the above (24) and (25) together, with probability at least $1 - (2 + e)/p^3$, there holds

$$(z_k^\top \mathbf{V}_{\gamma}^{-1} \mathbf{z}_j)^2 \leq (z_k^\top \mathbf{V}_{\gamma, -k}^{-1} \mathbf{z}_j)^2 \leq C(n + C \sqrt{n \log p}) \log p.$$

By a similar argument with the fact that $\|\mathbf{V}_{\gamma, -k}^{-2}\| \leq 1$, we can have with probability at least $1 - (2 + e)/p^3$

$$(z_k^\top \mathbf{V}_{\gamma}^{-2} \mathbf{z}_j)^2 \leq 2 \left( (z_k^\top \mathbf{V}_{\gamma, -k}^{-2} \mathbf{z}_j)^2 + (z_k^\top \mathbf{V}_{\gamma, -k}^{-1} \mathbf{z}_j)^2 \right) \leq 4C(n + C \sqrt{n \log p}) \log p,$$

for some absolute constant $C$.

Above inequalities imply that with probability at least $1 - (2 + e)/p$, there hold

$$\max_{k \neq j} |z_k^\top \mathbf{V}_{\gamma}^{-1} \mathbf{z}_j|^2 \leq C(n + C \sqrt{n \log p}) \log p,$$

and

$$\max_{k \neq j} |z_k^\top \mathbf{V}_{\gamma}^{-2} \mathbf{z}_j|^2 \leq 4C(n + C \sqrt{n \log p}) \log p.$$

Then, there follows that

$$\max_{k \neq j} |z_k^\top \mathbf{V}_{\gamma}^{-1} \mathbf{z}_j|^2 = O_P(n \log p) \quad \text{and} \quad \max_{k \neq j} |z_k^\top \mathbf{V}_{\gamma}^{-2} \mathbf{z}_j|^2 = O_P(n \log p).$$

Then, we have

$$\text{Var}[A_1 | \mathbf{Z}] = 2 \sum_{k \neq j} \beta_k^2 \beta_j^2 (z_k^\top \mathbf{V}_{\gamma}^{-1} \mathbf{z}_j)^2 \leq 2 \max_{k \neq j} |z_k^\top \mathbf{V}_{\gamma}^{-1} \mathbf{z}_j|^2 \|\beta\|^4 = O_P(n \log n),$$

and similarly $\text{Var}[A_2 | \mathbf{Z}] = O_P(n \log n)$. By Chebyshev’s inequality, for any $\delta > 0$, we have

$$\mathbb{P} \left\{ \frac{1}{n} A_1 - \mathbb{E} \left[ \frac{1}{n} A_1 | \mathbf{Z} \right] > \delta \right\} \leq \frac{\text{Var} \left[ \frac{1}{n} A_1 | \mathbf{Z} \right]}{\delta^2} \to 0 \quad \text{as} \quad n \to \infty.$$

It then follows, by the dominated convergence theorem, that

$$\mathbb{P} \left\{ \left| \frac{1}{n} A_1 - \mathbb{E} \left[ \frac{1}{n} A_1 | \mathbf{Z} \right] \right| > \delta \right\} \to 0$$

which implies $n^{-1} A_1 - \mathbb{E} \left[ n^{-1} A_1 | \mathbf{Z} \right] = o_P(1)$. Similarly, we can have $n^{-1} A_2 - \mathbb{E} \left[ n^{-1} A_2 | \mathbf{Z} \right] = o_P(1)$. 

19
Next, let’s consider $B_1$ and $B_2$. Since it is easy to obtain $E[B_1|Z] = E[B_2|Z] = 0$, it suffices to control $\text{Var}[B_1|Z] = E[B_1^2|Z]$ and $\text{Var}[B_2|Z] = E[B_2^2|Z]$. Note that

$$B_1^2 = \sum_{k=1}^{p} \sum_{j=1}^{p} \beta_k \beta_j \xi_k \xi_j (\varepsilon^\top V_{\gamma}^{-1} z_k)(z_j^\top V_{\gamma}^{-1} \varepsilon).$$

The independence between $\xi_k$, $\xi_j$ ($k \neq j$) and $\varepsilon$ implies that

$$E[B_1^2|Z] = \sum_{k=1}^{p} \beta_k^2 E[\varepsilon^\top V_{\gamma}^{-1} z_k z_k^\top V_{\gamma}^{-1} \varepsilon|Z].$$

$$= \sum_{k=1}^{p} \beta_k^2 \sigma_0^2 \text{trace}(V_{\gamma}^{-1} z_k z_k^\top V_{\gamma}^{-1}) \leq \sigma_0^2 \|\beta\|^2 \max_{1 \leq k \leq q} \|z_k\|^2$$

by the fact that $\|V_{\gamma}^{-1}\| \leq 1$. By (25), it implies that $\max_{1 \leq k \leq p} \|z_k\|^2 = O_P(n)$. Hence

$$\text{Var}[B_1|Z] \leq \sigma_0^2 \|\beta\|^2 \max_{1 \leq k \leq q} \|z_k\|^2 = O_P(n).$$

Then by Chebyshev’s inequality and the dominated convergence theorem, there holds

$$\mathbb{P}\left\{\left|\frac{1}{n}B_1\right| > \delta\right\} \to 0 \text{ as } n \to \infty,$$

which follows $n^{-1}B_1 = o_P(1)$. By a similar argument, we have $n^{-1}B_2 = o_P(1)$.

Let’s consider $C_1$ and $C_2$ now. By quadratic form, we have

$$E[C_1|Z] = \sigma_0^2 \text{trace}(V_{\gamma}^{-1}), \quad \text{Var}[C_1|Z] = \sigma_0^4 \text{trace}(V_{\gamma}^{-2}) = O_P(n)$$

and

$$E[C_2|Z] = \sigma_0^2 \text{trace}(V_{\gamma}^{-2}), \quad \text{Var}[C_2|Z] = \sigma_0^4 \text{trace}(V_{\gamma}^{-4}) = O_P(n).$$

Again, by Chebyshev’s inequality and the dominated convergence theorem, there holds

$$n^{-1}C_1 - E\left[n^{-1}C_1|Z\right] = o_P(1) \quad \text{and} \quad n^{-1}C_2 - E\left[n^{-1}C_2|Z\right] = o_P(1).$$

Combining the conclusions above, we have

$$|\Delta(\gamma) - \Delta_*(\gamma)| \leq \frac{1}{n^{-1}\text{trace}(I_n - V_{\gamma}^{-1})} \left|\frac{1}{n} (A_1 - E[A_1|Z]) + \frac{2}{n} (B_1 - E[B_1|Z]) + \frac{1}{n} (C_1 - E[C_1|Z])\right|$$

$$+ \frac{1}{n^{-1}\text{trace}(I_n - V_{\gamma}^{-1})n^{-1}\text{trace}(V_{\gamma}^{-1})} \left|\frac{1}{n} (A_2 - E[A_2|Z]) + \frac{2}{n} (B_2 - E[B_2|Z])\right|$$

$$+ \frac{1}{n} (C_2 - E[C_2|Z]) = o_P(1)$$

which means $\Delta(\gamma) - \Delta_*(\gamma) \xrightarrow{n \to \infty} 0$. 

20
4.2.2 Control of $\Delta_*(\gamma) - \Delta_{**}(\gamma)$

Recall that $\mathbb{E}[A_1|Z] = \sum_{k=1}^p \beta_k^2 (z_k^\top V_{\gamma}^{-1} z_k)$ and $\mathbb{E}[A_2|Z] = \sum_{k=1}^p \beta_k^2 (z_k^\top V_{\gamma}^{-2} z_k)$, so it is essential to calculate $z_k^\top V_{\gamma}^{-1} z_k$ and $z_k^\top V_{\gamma}^{-2} z_k$. Based on (21) and (22), there holds

$$z_k^\top V_{\gamma}^{-1} z_k = (1 + \frac{\gamma}{p} \rho_k)^{-1} \rho_k,$$

$$z_k^\top V_{\gamma}^{-2} z_k = (1 + \frac{\gamma}{p} \rho_k)^{-2} \phi_k,$$

where $\rho_k$ and $\phi_k$ are defined in (20).

We first formalize the intuitions $\rho_k \approx \text{trace}(V_{\gamma,-k}^{-1})$ and $\phi_k \approx \text{trace}(V_{\gamma,-k}^{-2})$ for all $k$. Since the entries of $Z$ are independent sub-Gaussian and $\mathbb{E}(z_{ik}) = 0$, using Proposition 4.3, we have, for any $1 \leq k \leq p$ and $t > 0$:

$$\mathbb{P}\left\{ |\rho_k - \text{trace}(V_{\gamma,-k}^{-1})| > t |V_{\gamma,-k}\right\} \leq 2 \exp \left\{-c \min\left(\frac{t^2}{K^4\|V_{\gamma,-k}^{-1}\|_F^2}, \frac{t}{K^2\|V_{\gamma,-k}^{-1}\|}\right)\right\},$$

where $c$ and $K$ are positive constants. If we set

$$t = t_k = K^2 \max \left(\sqrt{\frac{2 \log p}{c} \|V_{\gamma,-k}^{-1}\|_F}, \frac{2 \log p}{c} \|V_{\gamma,-k}^{-1}\|\right),$$

it follows that $\mathbb{P}\left\{ |\rho_k - \text{trace}(V_{\gamma,-k}^{-1})| > t_k |V_{\gamma,-k}\right\} \leq 2/p^2$; thus

$$\mathbb{P}\left\{ \max_{1 \leq k \leq p} |\rho_k - \text{trace}(V_{\gamma,-k}^{-1})| > t_k\right\} \leq \frac{2}{p}.$$

Using the fact that $\|V_{\gamma,-k}^{-1}\| \leq 1$, and $\|V_{\gamma,-k}^{-1}\|_F \leq \sqrt{n} \|V_{\gamma,-k}^{-1}\| \leq \sqrt{n}$, we can obtain that

$$t_k \leq K^2 \max \left(\sqrt{\frac{2}{c} \sqrt{n \log p}}, \frac{2 \log p}{c} \right),$$

which implies

$$\mathbb{P}\left\{ \max_{1 \leq k \leq p} |\rho_k - \text{trace}(V_{\gamma,-k}^{-1})| > C \sqrt{n \log p}\right\} \leq 2/p$$

for some constant $C > 0$. Then, it follows that

$$\max_{1 \leq k \leq p} |\rho_k - \text{trace}(V_{\gamma,-k}^{-1})| = O_P(\sqrt{n \log n}).$$

(28)

By a similar argument, we have

$$\max_{1 \leq k \leq p} |\phi_k - \text{trace}(V_{\gamma,-k}^{-2})| = O_P(\sqrt{n \log n}).$$

(29)

By (21) and (22), we can also have

$$\text{trace}(V_{\gamma}^{-1}) = \text{trace}(V_{\gamma,-k}^{-1}) - \frac{2}{p} (1 + \frac{\gamma}{p} \rho_k)^{-1} \phi_k,$$
and
\[
\text{trace}(V_{\gamma}^{-2}) = \text{trace}(V_{\gamma, -k}^{-2}) - \frac{2\gamma}{p} (1 + \frac{\gamma}{p} \rho_k)^{-1} \psi_k + (\frac{\gamma}{p})^2 (1 + \frac{\gamma}{p} \rho_k)^{-2} \phi_k^2.
\]

Then
\[
\left| \text{trace}(V_{\gamma}^{-1}) - \text{trace}(V_{\gamma, -k}^{-1}) \right| = \frac{\gamma}{p} (1 + \frac{\gamma}{p} \rho_k)^{-1} \phi_k \leq \frac{\gamma}{p} (1 + \frac{\gamma}{p} \rho_k)^{-1} \rho_k < 1, \tag{30}
\]
and
\[
\left| \text{trace}(V_{\gamma}^{-2}) - \text{trace}(V_{\gamma, -k}^{-2}) \right| \leq \frac{2\gamma}{p} (1 + \frac{\gamma}{p} \rho_k)^{-1} \rho_k + (\frac{\gamma}{p})^2 (1 + \frac{\gamma}{p} \rho_k)^{-2} \rho_k^2 < 3. \tag{31}
\]
Furthermore, by (30), (28), (31) and (29), it can be shown that:
\[
\max_{1 \leq k \leq p} \left| \rho_k - \text{trace}(V_{\gamma}^{-1}) \right| = O_P(\sqrt{n \log n}), \quad \text{and} \quad \max_{1 \leq k \leq p} \left| \phi_k - \text{trace}(V_{\gamma}^{-2}) \right| = O_P(\sqrt{n \log n}). \tag{32}
\]

Let’s now come back to find approximations of \( \mathbb{E}[A_1|Z] \) and \( \mathbb{E}[A_2|Z] \). We define the following intermediate quantities
\[
\theta_1 = \frac{1}{n} \frac{\text{trace}(V_{\gamma}^{-1})}{1 + \frac{\gamma}{p} \text{trace}(V_{\gamma}^{-1})} \quad \text{and} \quad \theta_2 = \frac{1}{n} \frac{\text{trace}(V_{\gamma}^{-2})}{\left(1 + \frac{\gamma}{p} \text{trace}(V_{\gamma}^{-1})\right)^2}.
\]
Then by (26) and (32), we can have
\[
\max_{1 \leq k \leq p} \left| \theta_1 - \frac{z_k^T V_{\gamma}^{-1} z_k}{n} \right| \leq \max_{1 \leq k \leq p} \left| \frac{\text{trace}(V_{\gamma}^{-1}) - \rho_k}{n} \right| = O_P \left( \sqrt{\frac{\log n}{n}} \right). \tag{34}
\]
Similarly, by (27) and (33), there holds
\[
\max_{1 \leq k \leq p} \left| \theta_2 - \frac{z_k^T V_{\gamma}^{-2} z_k}{n} \right| \leq \max_{1 \leq k \leq p} \left| \frac{\text{trace}(V_{\gamma}^{-2}) \left(1 + \frac{\gamma}{p} \rho_k\right)^2 - \left(1 + \frac{\gamma}{p} \text{trace}(V_{\gamma}^{-1})\right)^2 \phi_k}{n} \right|
\]
\[
\leq \frac{1}{n} \left[ \max_{1 \leq k \leq p} \left| \text{trace}(V_{\gamma}^{-2}) - \phi_k \right| + \max_{1 \leq k \leq p} \frac{2\gamma}{p} \rho_k \left| \text{trace}(V_{\gamma}^{-2}) - \phi_k \right| \right.
\]
\[
+ \max_{1 \leq k \leq p} \frac{2\gamma}{p} \phi_k \left| \rho_k - \text{trace}(V_{\gamma}^{-1}) \right| + \max_{1 \leq k \leq p} \frac{\gamma^2}{p^2} \rho_k^2 \left| \text{trace}(V_{\gamma}^{-2}) - \phi_k \right|
\]
\[
+ \max_{1 \leq k \leq p} \frac{\gamma^2}{p^2} \phi_k \left| \rho_k - \text{trace}(V_{\gamma}^{-1}) \right| \left| \rho_k + \text{trace}(V_{\gamma}^{-1}) \right| \right].
\]
It follows, by the facts \( \text{trace}(V_{\gamma}^{-1}) = O_P(n), \text{trace}(V_{\gamma}^{-2}) = O_P(n), \rho_k = O_P(n) \) and \( \phi_k = O_P(n) \),
\[
\max_{1 \leq k \leq p} \left| \theta_2 - \frac{z_k^T V_{\gamma}^{-2} z_k}{n} \right| = O_P \left( \sqrt{\frac{\log n}{n}} \right). \tag{35}
\]
Then, it can be shown that, by (34) and the fact that \( \| \beta \|^2 = \sigma_0^2 \gamma_0 \),

\[
\left\| \beta \right\|^2 \theta_1 - \frac{1}{n} \mathbb{E}[A_1|Z] \leq \left\| \beta \right\|^2 \max_{1 \leq k \leq p} \left| \theta_1 - \frac{z_k^T V_{\gamma}^{-1} z_k}{n} \right| = O_P \left( \sqrt{\frac{\log n}{n}} \right).
\]

On the other hand, since \( \text{trace}(V_{\gamma}^{-1} ZZ^T) = \sum_{k=1}^{p} z_k^T V_{\gamma}^{-1} z_k \), we have

\[
\left| \theta_1 - \frac{1}{n} \text{trace}(V_{\gamma}^{-1} ZZ^T) \right| \leq \max_{1 \leq k \leq p} \left| \theta_1 - \frac{z_k^T V_{\gamma}^{-1} z_k}{n} \right| = O_P \left( \sqrt{\frac{\log n}{n}} \right).
\]

Combining the above inequalities, we have

\[
\left| \frac{1}{n} \mathbb{E}[A_1|Z] - \frac{\left\| \beta \right\|^2}{np} \text{trace}(V_{\gamma}^{-1} ZZ^T) \right| = O_P \left( \sqrt{\frac{\log n}{n}} \right).
\]

By a similar argument with (35), we can show that

\[
\left| \frac{1}{n} \mathbb{E}[A_2|Z] - \frac{\left\| \beta \right\|^2}{np} \text{trace}(V_{\gamma}^{-2} ZZ^T) \right| = O_P \left( \sqrt{\frac{\log n}{n}} \right).
\]

Therefore,

\[
\begin{align*}
|\Delta_*(\gamma) - \Delta_{**}(\gamma)| &\leq \frac{1}{n-1} \text{trace}(I_n - V_{\gamma}^{-1}) \left| \frac{1}{np} \mathbb{E}[A_1|Z] - \frac{\left\| \beta \right\|^2}{np} \text{trace}(V_{\gamma}^{-1} ZZ^T) \right| \\
&\quad + \frac{1}{n-1} \text{trace}(I_n - V_{\gamma}^{-1}) n^{-1} \text{trace}(V_{\gamma}^{-1}) \left| \frac{1}{n} \mathbb{E}[A_1|Z] - \frac{\left\| \beta \right\|^2}{np} \text{trace}(V_{\gamma}^{-1} ZZ^T) \right| \\
&= O_P \left( \sqrt{\frac{\log n}{n}} \right)
\end{align*}
\]

which means \( \Delta_*(\gamma) - \Delta_{**}(\gamma) \xrightarrow{P} 0 \).

**4.2.3** \( \Delta_{**}(\gamma) \xrightarrow{a.s.} c_{\gamma} \).

In this part, the case \( \tau \leq 1 \) has been exactly discussed in Jiang et al. (2016), but we give a self-contained proof for completeness. Recall that \( \Delta_{**}(\gamma) \) is of the form (15), so we need to study the asymptotics of \( \text{trace}(V_{\gamma}^{-1}) \), \( \text{trace}(V_{\gamma}^{-2}) \), \( \text{trace}(V_{\gamma}^{-1} ZZ^T) \) and \( \text{trace}(V_{\gamma}^{-2} ZZ^T) \).
Case 1: \( \tau \leq 1 \). Denoting by \( \lambda_k \) the eigenvalues of \( p^{-1}ZZ^\top \), by Corollary 4.1 and the fact that \( \gamma_0 = \|\beta\|^2/\sigma_0^2 \), we have

\[
\frac{\|\beta\|^2}{np} \text{trace} \left( V_{\gamma}^{-1}ZZ^\top \right) = \gamma_0 \sigma_0^2 \frac{1}{n} \sum_{k=1}^{n} \frac{\lambda_k}{1 + \gamma \lambda_k} \xrightarrow{a.s.} \gamma_0 \sigma_0^2 \int_{b_-}^{b_+} \frac{xf(x)\,dx}{1 + \gamma x},
\]

\[
\frac{\|\beta\|^2}{np} \text{trace} \left( V_{\gamma}^{-2}ZZ^\top \right) = \gamma_0 \sigma_0^2 \frac{1}{n} \sum_{k=1}^{n} \frac{\lambda_k}{(1 + \gamma \lambda_k)^2} \xrightarrow{a.s.} \gamma_0 \sigma_0^2 \int_{b_-}^{b_+} \frac{xf(x)\,dx}{(1 + \gamma x)^2},
\]

\[
\frac{1}{n} \text{trace} \left( V_{\gamma}^{-1} \right) = \frac{1}{n} \sum_{k=1}^{n} \frac{1}{(1 + \gamma \lambda_k)^2} \xrightarrow{a.s.} \int_{b_-}^{b_+} \frac{f(x)\,dx}{1 + \gamma x}.
\]

Then, there holds

\[
\Delta_{**}(\gamma) = \frac{1}{n^{-1} \text{trace}(I_n - V_{\gamma}^{-1})} \left( \frac{\|\beta\|^2}{np} \text{trace}(V_{\gamma}^{-1}ZZ^\top) + \frac{\sigma_0^2}{n} \text{trace}(V_{\gamma}^{-1}) \right) - \frac{1}{n^{-1} \text{trace}(I_n - V_{\gamma}^{-1})} \left( \frac{\|\beta\|^2}{np} \text{trace}(V_{\gamma}^{-2}ZZ^\top) + \frac{\sigma_0^2}{n} \text{trace}(V_{\gamma}^{-2}) \right)
\]

\[
\xrightarrow{a.s.} \sigma_0^2 \left( \frac{\gamma_0}{\gamma} - 1 \right) d_{\gamma,\tau},
\]

where

\[
d_{\gamma,\tau} = 1 - \frac{\int_{b_-}^{b_+} \frac{f(x)\,dx}{1 + \gamma x} - f_{b_+}(x) - f_{b_-}(x)}{\int_{b_-}^{b_+} \frac{f(x)\,dx}{1 + \gamma x} - \int_{b_-}^{b_+} \frac{f(x)\,dx}{1 + \gamma x} - f_{b_+}(x) - f_{b_-}(x)}^2.
\]

Since on \([b_-(\tau), b_+(\tau)]\), \( f_\tau(x) > 0 \), \( (1 + \gamma x)^{-1} \) are strictly decreasing \( \gamma > 0 \), we have, by monotone function inequalities [Jiang, 2010], pages 147-148],

\[
\left( \int_{b_-}^{b_+} \frac{f(x)\,dx}{1 + \gamma x} \right)^2 < \left( \int_{b_-}^{b_+} \frac{f(x)\,dx}{1 + \gamma x} \right) \left( \int_{b_-}^{b_+} \frac{f(x)\,dx}{1 + \gamma x} \right) = \int_{b_-}^{b_+} \frac{f(x)\,dx}{1 + \gamma x},
\]

which implies

\[
\frac{\int_{b_-}^{b_+} f(x)\,dx}{1 + \gamma x} - \int_{b_-}^{b_+} \frac{f(x)\,dx}{1 + \gamma x} < 1.
\]

Thus \( d_{\gamma,\tau} > 0 \).
Case 2: \( \tau > 1 \). By Corollary 4.1 and the fact that \( \gamma_0 = \|\beta\|^2 / \sigma_0^2 \), we can have

\[
\frac{||\beta||^2}{np} \text{trace} \left( V_{\gamma}^{-1} ZZ^\top \right) = \gamma_0 \sigma_0^2 \frac{1}{n} \sum_{k=1}^{n} \frac{\lambda_k}{1 + \gamma \lambda_k} \xrightarrow{a.s.} \gamma_0 \sigma_0^2 \int_{b_-(\tau)}^{b_+(\tau)} \frac{xf_\tau(x)}{1 + \gamma x} \, dx,
\]

\[
\frac{||\beta||^2}{np} \text{trace} \left( V_{\gamma}^{-2} ZZ^\top \right) = \gamma_0 \sigma_0^2 \frac{1}{n} \sum_{k=1}^{n} \frac{\lambda_k}{(1 + \gamma \lambda_k)^2} \xrightarrow{a.s.} \gamma_0 \sigma_0^2 \int_{b_-(\tau)}^{b_+(\tau)} \frac{xf_\tau(x)}{(1 + \gamma x)^2} \, dx,
\]

\[
\frac{1}{n} \text{trace} \left( V_{\gamma}^{-1} \right) = \frac{1}{n} \sum_{k=1}^{n} \frac{1}{1 + \gamma \lambda_k} \xrightarrow{a.s.} \int_{b_-(\tau)}^{b_+(\tau)} \frac{f_\tau(x)}{(1 + \gamma x)^2} \, dx + 1 - \frac{1}{\tau},
\]

\[
\frac{1}{n} \text{trace} \left( V_{\gamma}^{-2} \right) = \frac{1}{n} \sum_{k=1}^{n} \frac{1}{(1 + \gamma \lambda_k)^2} \xrightarrow{a.s.} \int_{b_-(\tau)}^{b_+(\tau)} \frac{f_\tau(x)}{(1 + \gamma x)^2} \, dx + 1 - \frac{1}{\tau}.
\]

Then we can show that

\[
\Delta_{**}(\gamma) = \frac{1}{n-1} \text{trace} \left( I_n - V_{\gamma}^{-1} \right) \left( \frac{||\beta||^2}{np} \text{trace} \left( V_{\gamma}^{-1} ZZ^\top \right) + \frac{\sigma_0^2}{n} \text{trace} \left( V_{\gamma}^{-1} \right) \right)
\]

\[
- \frac{1}{n-1} \text{trace} \left( I_n - V_{\gamma}^{-1} \right) \frac{||\beta||^2}{np} \text{trace} \left( V_{\gamma}^{-2} ZZ^\top \right) + \frac{\sigma_0^2}{n} \text{trace} \left( V_{\gamma}^{-2} \right)
\]

\[
\xrightarrow{a.s.} \sigma_0^2 \left( \frac{\gamma_0}{1} \int_{b_-(\tau)}^{b_+(\tau)} \frac{xf_\tau(x)}{1 + \gamma x} \, dx + \int_{b_-(\tau)}^{b_+(\tau)} \frac{f_\tau(x)}{1 + \gamma x} \, dx + 1 - \frac{1}{\tau} \right)
\]

\[
\xrightarrow{a.s.} \sigma_0^2 \left( \frac{\gamma_0}{1} \int_{b_-(\tau)}^{b_+(\tau)} \frac{xf_\tau(x)}{1 + \gamma x} \, dx + \int_{b_-(\tau)}^{b_+(\tau)} \frac{f_\tau(x)}{1 + \gamma x} \, dx + 1 - \frac{1}{\tau} \right)
\]

\[
= \sigma_0^2 \left( \frac{\gamma_0}{\gamma} - 1 \right) d_{\gamma, \tau},
\]

where

\[
d_{\gamma, \tau} = - \left( \frac{\int_{b_-(\tau)}^{b_+(\tau)} \frac{f_\tau(x)}{1 + \gamma x} \, dx + 1 - \frac{1}{\tau}}{\int_{b_-(\tau)}^{b_+(\tau)} \frac{f_\tau(x)}{1 + \gamma x} \, dx + 1 - \frac{1}{\tau}} \right)^2 - \left( \frac{\int_{b_-(\tau)}^{b_+(\tau)} \frac{f_\tau(x)}{1 + \gamma x} \, dx + 1 - \frac{1}{\tau}}{\int_{b_-(\tau)}^{b_+(\tau)} \frac{f_\tau(x)}{1 + \gamma x} \, dx + 1 - \frac{1}{\tau}} \right). \]
Since

\[
\left( \int_{b_-(\tau)}^{b_+(\tau)} \frac{f_{\tau}(x)}{1 + \gamma x} \, dx + 1 - \frac{1}{\tau} \right)^2 - \left( \int_{b_-(\tau)}^{b_+(\tau)} \frac{f_{\tau}(x)}{(1 + \gamma x)^2} \, dx + 1 - \frac{1}{\tau} \right) \\
= \left( \int_{b_-(\tau)}^{b_+(\tau)} \frac{f_{\tau}(x)}{1 + \gamma x} \, dx \right)^2 + 2 \left( 1 - \frac{1}{\tau} \right) \int_{b_-(\tau)}^{b_+(\tau)} \frac{f_{\tau}(x)}{(1 + \gamma x)^2} \, dx + \left( 1 - \frac{1}{\tau} \right)^2 \\
- \int_{b_-(\tau)}^{b_+(\tau)} \frac{f_{\tau}(x)}{(1 + \gamma x)^2} \, dx - \left( 1 - \frac{1}{\tau} \right) \int_{b_-(\tau)}^{b_+(\tau)} \frac{f_{\tau}(x)}{1 + \gamma x} \, dx + \left( 1 - \frac{1}{\tau} \right) \\
< \left( 1 - \frac{1}{\tau} \right) \left( 2 \int_{b_-(\tau)}^{b_+(\tau)} \frac{f_{\tau}(x)}{1 + \gamma x} \, dx - \int_{b_-(\tau)}^{b_+(\tau)} \frac{f_{\tau}(x)}{(1 + \gamma x)^2} \, dx - 1 - \frac{1}{\tau} \right) \\
= \left( 1 - \frac{1}{\tau} \right) \left( \int_{b_-(\tau)}^{b_+(\tau)} \frac{1 + 2 \gamma x}{1 + 2 \gamma x + \gamma^2 x^2} f_{\tau}(x) \, dx - \frac{1}{\tau} \right) \\
< \left( 1 - \frac{1}{\tau} \right) \left( \int_{b_-(\tau)}^{b_+(\tau)} f_{\tau}(x) \, dx - \frac{1}{\tau} \right) = 0,
\]

where the first inequality is due to \( \left( \int_{b_-(\tau)}^{b_+(\tau)} \frac{f_{\tau}(x)}{1 + \gamma x} \, dx \right)^2 < \int_{b_-(\tau)}^{b_+(\tau)} \frac{f_{\tau}(x)}{(1 + \gamma x)^2} \, dx \). The denominator is positive since

\[- \int_{b_-(\tau)}^{b_+(\tau)} \frac{f_{\tau}(x)}{1 + \gamma x} \, dx + \frac{1}{\tau} > - \int_{b_-(\tau)}^{b_+(\tau)} f_{\tau}(x) \, dx + \frac{1}{\tau} = 0.\]

With the above inequalities, we conclude \( d_{\gamma, \tau} > 0 \).

Then it is shown that for both \( \tau < 1 \) and \( \tau > 1 \), the limit of \( \Delta_{\ast\ast}(\gamma) \) is \( c_{\gamma} = \sigma_0^2 \left( \frac{\alpha}{\gamma} - 1 \right) d_{\gamma}, \) which is \( > 0, = 0 \) or \( < 0 \) depending on whether \( \gamma \) is \( < \gamma_0, = \gamma_0 \) or \( > \gamma_0 \).

### 4.2.4 Completing the proof of Theorem 2.1

We have shown that \( \Delta(\gamma) - \Delta_*(\gamma) \xrightarrow{P} 0 \), \( \Delta_*(\gamma) - \Delta_{\ast\ast}(\gamma) \xrightarrow{P} 0 \) and \( \Delta_{\ast\ast}(\gamma) \xrightarrow{a.s.} c_{\gamma} \), which give that for any \( \delta > 0 \), there holds \( \Delta(\gamma) \xrightarrow{P} c_{\gamma} \), where is \( > 0, = 0 \) or \( < 0 \) depending on whether \( \gamma \) is \( < \gamma_0, = \gamma_0 \) or \( > \gamma_0 \). Then by the argument of Theorem 3.7 in Lehmann and Casella (2006), the equation \( \Delta(\gamma|y) = 0 \) has a root \( \gamma_n \) tending to the \( \gamma_0 \) in probability.

Finally, let’s show \( \hat{\sigma}_n^2 \xrightarrow{P} \sigma_0^2 \), where the noise variance estimate is defined in (7). Let \( s_n(\gamma) = \frac{1}{n} y^\top V^{-1}_t y \). The noise variance estimate is then \( \hat{\sigma}^2 = s_n(\hat{\gamma}) \). From the previous sections, we know \( s_n(\gamma) \) converges to a continuous function \( \bar{s}(\gamma) \) in probability. For example, if \( \tau < 1 \), we have

\[
\bar{s}(\gamma) = \sigma_0^2 \int_{b_-(\tau)}^{b_+(\tau)} \left( 1 + \gamma_0 x \right) f_{\tau}(x) \, dx,
\]

which gives \( \bar{s}(\gamma_0) = \sigma_0^2 \).

An important observation is that \( s_n(\gamma) \) is decreasing. For any small \( \delta > 0 \) and \( \epsilon > 0 \), we know

\[
s_n(\gamma - \delta) \leq \bar{s}(\gamma - \delta) + \epsilon \quad \text{and} \quad s_n(\gamma + \delta) \leq \bar{s}(\gamma + \delta) - \epsilon
\]
with probability tending to 1. On the other hand, \( \hat{\gamma}_n \to \gamma_0 \) in probability implies that 
\( \gamma_0 - \delta < \hat{\gamma}_n < \gamma_0 + \delta \) with probability tending to 1. Therefore, we have
\[
\bar{s}(\gamma_0 - \delta) + \epsilon \geq s_n(\gamma_0 - \delta) \geq s_n(\hat{\gamma}_n) \geq s_n(\gamma_0 + \delta) \geq \bar{s}(\gamma_0 + \delta) - \epsilon
\]
with probability tending to 1. Since \( \delta \) and \( \epsilon \) can be arbitrarily small, we have
\[
s_n(\hat{\gamma}_n) \xrightarrow{P} \bar{s}(\gamma_0) = \sigma_0^2.
\]

### 4.3 Proof of Theorem 2.2

For the linear model with a partitioned design (8), the likelihood functions with respect to
the vector of SNR \( \gamma \) have been given in (12), i.e.,
\[
\Delta^{(i)}(\gamma) = \frac{1}{n} y^\top V_\gamma^{-1} \left( \frac{1}{p_i} Z_i Z_i^\top \right) V_\gamma^{-1} y - \frac{1}{n} y^\top V_\gamma^{-2} y - \frac{1}{p_i} Z_i Z_i^\top V_\gamma^{-1} \left( \sum_{r=1}^{p_r} \beta_{rk} \xi_{ik} z_{rk} \right),
\]
(36)

Our goal is to show that the asymptotic limit of \( \Delta^{(i)}(\gamma_0) \) is 0. Following the proof ideas
for Theorem 2.1, we also use the trick of Rademacher sequences, which means the response
vector can be represented as
\[
y = \sum_{i=1}^{s} \left( \sum_{k=1}^{p_i} \beta_{ik} \xi_{ik} z_{ik} \right) + \epsilon.
\]
For \( i = 1, \ldots, s \), let
\[
A^{(i)} := \left( \sum_{r=1}^{s} \left( \sum_{k=1}^{p_r} \beta_{rk} \xi_{rk} z_{rk} \right) \right)^\top V_\gamma^{-1} \left( \sum_{r=1}^{p_r} \beta_{rk} \xi_{rk} z_{rk} \right),
\]
\[
B^{(i)} := \left( \sum_{r=1}^{s} \left( \sum_{k=1}^{p_r} \beta_{rk} \xi_{rk} z_{rk} \right) \right)^\top V_\gamma^{-1} \left( \sum_{r=1}^{p_r} \beta_{rk} \xi_{rk} z_{rk} \right),
\]
\[
C^{(i)} := \epsilon^\top V_\gamma^{-1} \left( \sum_{r=1}^{p_r} \beta_{rk} \xi_{rk} z_{rk} \right) \epsilon,
\]
and
\[
A^{(0)} := \left( \sum_{r=1}^{s} \left( \sum_{k=1}^{p_r} \beta_{rk} \xi_{rk} z_{rk} \right) \right)^\top V_\gamma^{-2} \left( \sum_{r=1}^{s} \left( \sum_{k=1}^{p_r} \beta_{rk} \xi_{rk} z_{rk} \right) \right),
\]
\[
B^{(0)} := \left( \sum_{r=1}^{s} \left( \sum_{k=1}^{p_r} \beta_{rk} \xi_{rk} z_{rk} \right) \right)^\top V_\gamma^{-2} \epsilon,
\]
\[
C^{(0)} := \epsilon^\top V_\gamma^{-2} \epsilon.
\]
Recall that we have also defined
\[ \Delta^*(\gamma) := \frac{\frac{1}{n} \left( \frac{1}{p_i} \right) (\gamma_i - \gamma_0 i) \left( \frac{1}{p_i} \right) (\gamma_i - \gamma_0 i)}{\frac{1}{n} \left( \frac{1}{p_i} \right) (\gamma_i - \gamma_0 i) \left( \frac{1}{p_i} \right) (\gamma_i - \gamma_0 i)} - \frac{\frac{1}{n} \left( \frac{1}{p_i} \right) (\gamma_i - \gamma_0 i) \left( \frac{1}{p_i} \right) (\gamma_i - \gamma_0 i)}{\frac{1}{n} \left( \frac{1}{p_i} \right) (\gamma_i - \gamma_0 i) \left( \frac{1}{p_i} \right) (\gamma_i - \gamma_0 i)}. \]

(37)

We will follow the arguments for the standard linear model to show \( \Delta^*(\gamma) - \Delta^*(\gamma) \rightarrow 0 \) and \( \Delta^*(\gamma) - \Delta^*(\gamma) \rightarrow 0 \).

4.3.1 Control of \( \Delta^*(\gamma) - \Delta^*(\gamma) \)

First, for \( i = 1, \ldots, s \), we aim to control
\[ \text{Var}[A^i[Z] = E[(A^i)^2[Z]} - E[A^i[Z]]^2, \]
and then give a control of \( A^i - E[A^i[Z] \) by Chebyshev’s inequality. For convenience of calculation, define
\[ M_i := \frac{1}{p_i} V_{\gamma i}^{-1} Z_i Z_i^\top V_{\gamma i}^{-1}. \]

Recall that
\[ A^i = \left( \sum_{r=1}^{s} \left( \sum_{k=1}^{p_r} \beta_{rk} \xi_{rk} z_{rk} \right) \right)^\top M_i \left( \sum_{r=1}^{s} \left( \sum_{k=1}^{p_r} \beta_{rk} \xi_{rk} z_{rk} \right) \right).
\]

Define
\[ g_{r_1 k, r_2 j, r_3 l, r_4 m} := \beta_{r_1 k} \beta_{r_2 j} \beta_{r_3 l} \beta_{r_4 m} \xi_{r_1 k} \xi_{r_2 j} \xi_{r_3 l} \xi_{r_4 m} (z_{r_1 k}^\top M_i z_{r_2 j}) (z_{r_3 l}^\top M_i z_{r_4 m}) . \]
Then
\[
(A^{(i)})^2 = \sum_{r=1}^{s} \sum_{k=1}^{p_r} \sum_{l=1}^{p_r} \sum_{m=1}^{p_r} g_{r,k,r,l,rm}^{(i)} + \sum_{r<t} \sum_{k=1}^{p_r} \sum_{l=1}^{p_r} \sum_{m=1}^{p_r} g_{r,k,t,l,tm}^{(i)} + \sum_{r<t} \sum_{k=1}^{p_r} \sum_{l=1}^{p_r} \sum_{m=1}^{p_r} g_{r,k,r,l,tm}^{(i)}
\]
\[
+ \sum_{r<t} \sum_{k=1}^{p_r} \sum_{l=1}^{p_r} \sum_{m=1}^{p_r} g_{r1,k,t1,j2,l2m}^{(i)}
\]
\[
+ \sum_{r\neq t} \sum_{k=1}^{p_r} \sum_{l=1}^{p_r} \sum_{m=1}^{p_r} g_{r,k,r,l,tm}^{(i)}.
\]

Since \(\xi_{r,k}\)'s are Rademacher random variables, if \((r_1, k, r_2, j, r_3, l, r_4, m)\) has an odd multiplicity, we have \(\mathbb{E}[\xi_{r_1,k}\xi_{r_2,j}\xi_{r_3,l}\xi_{r_4,m}] = 0\), i.e. \(\mathbb{E}[g_{r_1,k,r_2,j,r_3,l,r_4,m}^{(i)}] = 0\). Thus we have
\[
\mathbb{E}[A^{(i)}|Z] = \sum_{r=1}^{s} \left( \sum_{k=1}^{p_r} \beta_{rk}^2 (z_{rk}^\top M_i z_{rk}) (z_{rk}^\top M_i z_{rk}) \right),
\]
which implies
\[
\left( \mathbb{E}[A^{(i)}|Z] \right)^2 = \sum_{r=1}^{s} \left( \sum_{k=1}^{p_r} \beta_{rk}^4 (z_{rk}^\top M_i z_{rk})^2 + \sum_{k\neq j} \beta_{rk}^2 \beta_{rj}^2 (z_{rk}^\top M_i z_{rk}) (z_{rj}^\top M_i z_{rk}) \right)
\]
\[
+ 2 \sum_{r<t} \sum_{k=1}^{p_r} \sum_{l=1}^{p_r} \beta_{rk}^2 \beta_{rj}^2 (z_{rk}^\top M_i z_{rk}) (z_{rj}^\top M_i z_{rk})
\]
\[
+ 2 \sum_{r<t} \sum_{k=1}^{p_r} \sum_{l=1}^{p_r} \beta_{rk}^2 \beta_{rj}^2 (z_{rk}^\top M_i z_{rk}) (z_{rj}^\top M_i z_{rj}).
\]

Then, we can get
\[
\text{Var}[A^{(i)}|Z] = \mathbb{E}[(A^{(i)})^2|Z] - \left( \mathbb{E}[A^{(i)}|Z] \right)^2
\]
\[
= 2 \sum_{r=1}^{s} \sum_{k<j} \beta_{rk}^2 \beta_{rj}^2 (z_{rk}^\top M_i z_{rj})^2 + 4 \sum_{r<t} \sum_{k=1}^{p_r} \sum_{l=1}^{p_r} \beta_{rk}^2 \beta_{rj}^2 (z_{rk}^\top M_i z_{rj})^2.
\]
By a similar argument, we can have that
\[
\text{Var}\left[ A^{(0)} | Z \right] = \mathbb{E} \left[ (A^{(0)})^2 | Z \right] - \left( \mathbb{E} \left[ A^{(0)} | Z \right] \right)^2
\]
\[
= 2 \sum_{r=1}^{s} \sum_{k<j} \beta^2_{rk} \beta^2_{rj} \left( z_{rk}^\top V^{-2}_\gamma z_{rj} \right)^2 + 4 \sum_{r<r' < t<k<j} \beta^2_{rk} \beta^2_{r'k} \left( z_{rk}^\top V^{-2}_\gamma z_{r'k} \right)^2.
\]

Recall that \( M_i = V^{-1}_\gamma \left( \frac{1}{p_i} Z_i Z_i^\top \right) V^{-1}_\gamma \) and \( t \neq r \).

**Case 1:** \( r \neq i \) and \( t \neq i \). We have
\[
z_{rk}^\top M_i z_{rj} = z_{rk}^\top V^{-1}_\gamma \left( \frac{1}{p_i} Z_i Z_i^\top \right) V^{-1}_\gamma z_{rj} = \frac{1}{p_i} \sum_{l=1}^{p_i} \left( z_{rk}^\top V^{-1}_\gamma z_{il} \right) \left( z_{il}^\top V^{-1}_\gamma z_{rj} \right),
\]
and
\[
z_{rk}^\top M_i z_{lj} = z_{rk}^\top V^{-1}_\gamma \left( \frac{1}{p_i} Z_i Z_i^\top \right) V^{-1}_\gamma z_{lj} = \frac{1}{p_i} \sum_{l=1}^{p_i} \left( z_{rk}^\top V^{-1}_\gamma z_{il} \right) \left( z_{il}^\top V^{-1}_\gamma z_{lj} \right).
\]

**Case 2:** \( r = i \), then \( t \neq i \). There holds
\[
z_{rk}^\top M_i z_{rj} = z_{ik}^\top M_i z_{ij} = \frac{1}{\gamma_i} z_{ik}^\top V^{-1}_\gamma z_{ij} - \frac{1}{\gamma_i} z_{ik}^\top V^{-2}_\gamma z_{ij} - \frac{1}{\gamma_i p_m} \sum_{m \neq i} \gamma_m p_m \sum_{l=1}^{p_m} \left( z_{ik}^\top V^{-1}_\gamma z_{ml} \right) \left( z_{ml}^\top V^{-1}_\gamma z_{lj} \right)
\]
by the fact \( p_i^{-1} Z_i Z_i^\top = \gamma_i^{-1} \left( V_\gamma - I_n - \sum_{m \neq i} p_m^{-1} \gamma_m Z_m Z_m^\top \right) \). We also have
\[
z_{rk}^\top M_i z_{lj} = z_{ik}^\top M_i z_{lj} = \frac{1}{p_i} \sum_{l \neq k} \left( z_{ik}^\top V^{-1}_\gamma z_{il} \right) \left( z_{il}^\top V^{-1}_\gamma z_{lj} \right) + \left( z_{ik}^\top V^{-1}_\gamma z_{ik} \right) \left( z_{ik}^\top V^{-1}_\gamma z_{ij} \right).
\]

**Case 3:** \( t = i \), then \( r \neq i \). There hold
\[
z_{rk}^\top M_i z_{rj} = \frac{1}{p_i} \sum_{l=1}^{p_i} \left( z_{rk}^\top V^{-1}_\gamma z_{il} \right) \left( z_{il}^\top V^{-1}_\gamma z_{rj} \right),
\]
and
\[
z_{rk}^\top M_i z_{lj} = z_{rk}^\top M_i z_{lj} = \frac{1}{p_i} \sum_{l \neq j} \left( z_{rk}^\top V^{-1}_\gamma z_{il} \right) \left( z_{il}^\top V^{-1}_\gamma z_{lj} \right) + \left( z_{rk}^\top V^{-1}_\gamma z_{lj} \right) \left( z_{lj}^\top V^{-1}_\gamma z_{lj} \right).
\]

To deal with \( z_{rk}^\top V^{-1}_\gamma z_{r2j} \) when \( (r_1, k) \neq (r_2, j) \), we can define
\[
V_{\gamma, -ik} = I_n + \frac{\gamma_i}{p_i} \sum_{l \neq k} z_{il}(z_{il})^\top + \sum_{r \neq i} \frac{\gamma_r}{p_r} Z_r Z_r^\top
\]
and
\[
\rho_{ik} := z_{ik}^\top V_{\gamma, -ik}^{-1} z_{ik}, \quad \phi_{ik} := z_{ik}^\top V_{\gamma, -ik}^{-2} z_{ik}.
\]
Using Sherman-Morrison-Woodbury formula, we have
\[ V_{\gamma}^{-1} = V_{\gamma,-ik}^{-1} - \frac{\gamma_i}{p_i} (1 + \frac{\gamma_i}{p_i} \rho_{ik})^{-1} V_{\gamma,-ik} z_{ik} V_{\gamma,-ik}^{\top}, \]
(38)
which implies that
\[ (z_{r_{ik}} V_{\gamma}^{-1} z_{r_{2j}})^2 = (1 + \frac{\gamma_i}{p_i} \rho_{ik})^{-2} z_{ik} V_{\gamma,-ik} z_{r_{2j}} V_{\gamma,-ik} z_{ik} \leq (z_{r_{ik}} V_{\gamma,-r_{ik}} z_{r_{2j}})^2, \]
and similar to (23)
\[ (z_{r_{ik}} V_{\gamma}^{-2} z_{r_{2j}})^2 \leq 2 \left( (z_{r_{ik}} V_{\gamma,-r_{ik}} z_{r_{2j}})^2 + (z_{r_{ik}} V_{\gamma,-r_{ik}} z_{r_{2j}})^2 \right). \]
(40)

Then by Hoeffding-type inequality in single-design, we can have for \((r_1, k) \neq (r_2, j),\)
\[ \mathbb{P} \left( |z_{r_{ik}} V_{\gamma,-r_{ik}} z_{r_{2j}}| \geq C \sqrt{\log p_{r_1}} \| V_{\gamma,-r_{ik}} z_{r_{2j}} \| \right) \leq \frac{\epsilon}{p_{r_1}^2}. \]
Since \(\| V_{\gamma,-r_{ik}} \| \leq 1\) for any \(1 \leq r \leq s, 1 \leq k \leq p_r,\) we have \(\| V_{\gamma,-r_{ik}} z_{r_{2j}} \| \leq \| z_{r_{2j}} \|.\) Then, by the Bernstein-type inequality,
\[ \mathbb{P} \left( \| z_{r_{2j}} \|^2 - n \geq C \sqrt{n \log p_{r_2}} \right) \leq \frac{1}{p_{r_2}^2}. \]
Combining the above inequalities we can show that
\[ \max_{(r_1, k) \neq (r_2, j)} |z_{r_{ik}} V_{\gamma,-r_{ik}} z_{r_{2j}}| = O_P(\sqrt{n \log n}). \]
Similarly, since \(\| V_{\gamma,-r_{ik}} \| \leq 1,\) there holds
\[ \max_{(r_1, k) \neq (r_2, j)} |z_{r_{ik}} V_{\gamma,-r_{ik}} z_{r_{2j}}| = O_P(\sqrt{n \log n}). \]
By (39) and (40), there hold
\[ \max_{(r_1, k) \neq (r_2, j)} |z_{r_{ik}} V_{\gamma}^{-1} z_{r_{2j}}| = O_P(\sqrt{n \log n}) \quad \text{and} \quad \max_{(r_1, k) \neq (r_2, j)} |z_{r_{ik}} V_{\gamma}^{-2} z_{r_{2j}}| = O_P(\sqrt{n \log n}). \]

We then calculate \(z_{ik} V_{\gamma}^{-1} z_{ik}\) and \(z_{ik} V_{\gamma}^{-2} z_{ik}\) by a similar argument in the proof of Theorem 2.1. Based on (38) we can have
\[ z_{ik} V_{\gamma}^{-1} z_{ik} = \frac{\rho_{ik}}{1 + \frac{\gamma_i}{p_i} \rho_{ik}}, \quad z_{ik} V_{\gamma}^{-2} z_{ik} = \frac{\phi_{ik}}{1 + \frac{\gamma_i}{p_i} \rho_{ik}}. \]
As with the proof of Theorem 2.1, by Proposition 4.3, we are able to show
\[ \max_{1 \leq k \leq p_i} |\rho_{ik} - \text{trace}(V_{\gamma}^{-1})| = O_P \left( \sqrt{n \log n} \right), \quad \text{and} \quad \max_{1 \leq k \leq p_i} |\phi_{ik} - \text{trace}(V_{\gamma}^{-2})| = O_P \left( \sqrt{n \log n} \right). \]
Then similar to (34) and (35), we actually have
\[
\max_{1 \leq k \leq p_i} \left| \frac{z_{ik}^\top V_{\gamma}^{-1} z_{ik} - \text{trace}(V_{\gamma}^{-1})}{1 + \frac{\gamma}{p_i} \text{trace}(V_{\gamma}^{-1})} \right| = O_P \left( \sqrt{n \log n} \right), \quad \text{and} \quad (41)
\]
\[
\max_{1 \leq k \leq p_i} \left| \frac{z_{ik}^\top V_{\gamma}^{-2} z_{ik} - \text{trace}(V_{\gamma}^{-2})}{\left( 1 + \frac{\gamma}{p_i} \text{trace}(V_{\gamma}^{-1}) \right)^2} \right| = O_P \left( \sqrt{n \log n} \right). \quad (42)
\]

The fact \( \text{trace}(V_{\gamma}^{-1}) \leq n \) and \( \text{trace}(V_{\gamma}^{-2}) \leq n \) further implies
\[
\max_{1 \leq k \leq p_i} \left| z_{ik}^\top V_{\gamma}^{-1} z_{ik} \right| = O_P(n), \quad \text{and} \quad \max_{1 \leq k \leq p_i} \left| z_{ik}^\top V_{\gamma}^{-2} z_{ik} \right| = O_P(n).
\]

Combining the above stochastic bounds, there hold
\[
\text{Var} \left[ A^{(i)} | Z \right] = O_P(n \sqrt{n \log n}) \quad (43)
\]
and
\[
\text{Var} \left[ A^{(0)} | Z \right] = O_P(n \sqrt{n \log n}). \quad (44)
\]

Hoeffding-type inequality in single-design gives that for \((r_1, k) \neq (r_2, j)\)
\[
P \left( \left| z_{r_1 k}^\top V_{\gamma}^{-2} z_{r_2 j} - \text{trace}(V_{\gamma}^{-2}) \right| \geq C \sqrt{\log p_{r_1} \| V_{\gamma}^{-2} z_{r_2 j} \|} \right) \leq \frac{e}{p_{r_1}},
\]
which further implies that
\[
\max_{(r_1, k) \neq (r_2, j)} \left| z_{r_1 k}^\top V_{\gamma}^{-2} z_{r_2 j} \right| = O_P(\sqrt{n \log n}).
\]

Coming to \(B^{(i)}\) and \(C^{(i)}\), we first have
\[
(B^{(i)})^2 = \sum_{r=1}^{s} \sum_{k=1}^{p_r} \sum_{j=1}^{p_r} \beta_{r k} \beta_{r j} \left( \mathbf{e}^\top \mathbf{M}_i z_{r k} z_{r j}^\top \mathbf{M}_i \mathbf{e} \right) \xi_{r k} \xi_{r j} + \sum_{r < t} \sum_{k=1}^{p_r} \sum_{j=1}^{p_t} \beta_{r k} \beta_{t j} \left( \mathbf{e}^\top \mathbf{M}_i z_{r k} z_{t j}^\top \mathbf{M}_i \mathbf{e} \right) \xi_{r k} \xi_{t j}.
\]

By the fact that \( \mathbb{E} [\xi_{r k} \xi_{r t}] = 0 \) when \( r < t \), we can get
\[
\text{Var} \left[ B^{(i)} | Z \right] = \sum_{r=1}^{s} \mathbb{E} \left[ B^{(i,r)} | Z \right],
\]
where
\[
B^{(i,r)} = \sum_{k=1}^{p_r} \sum_{j=1}^{p_r} \beta_{r k} \beta_{r j} \left( \mathbf{e}^\top \mathbf{M}_i z_{r k} z_{r j}^\top \mathbf{M}_i \mathbf{e} \right) \xi_{r k} \xi_{r j}.
\]

32
Then we have

\[
\mathbb{E} \left[ B^{(i,r)} | Z \right] = \sum_{k=1}^{p_r} \beta_{rk}^2 \sigma_0^2 \text{trace} \left( M_i z_{rk} z_{rk}^\top M_i \right) \leq \sigma_0^2 \| \beta_r \|^2 \| M_i^2 \| \| z_{rk} \|^2.
\]

The fact

\[
\lambda_{\text{max}} (M_i) = \lambda_{\text{max}} \left( \frac{1}{\gamma_i} V^{-1} \left( V \gamma - I_n - \sum_{r \neq i} \frac{\gamma_r}{p_r} Z_r Z_r^\top V \right) V^{-1} \right) \leq \frac{1}{\gamma_i} \lambda_{\text{max}} (V^{-1}) \leq \frac{1}{\gamma_i},
\]

implies

\[
\mathbb{E} \left[ B^{(i,r)} | Z \right] \leq \frac{\sigma_0^2}{\gamma_i^2} \| z_{rk} \|^2 = O_p(n).
\]

By (45), there holds

\[
\text{Var} \left[ B^{(i)} | Z \right] = O_p(n). 
\]

Similarly, we can have

\[
\text{Var} \left[ B^{(0)} | Z \right] = \sum_{r=1}^{s} \mathbb{E} \left[ B^{(0,r)} | Z \right] = \sum_{r=1}^{p_r} \beta_{rk}^2 \sigma_0^2 \text{trace} \left( V_{\gamma}^{-2} z_{rk} z_{rk}^\top V_{\gamma}^{-2} \right)
\]

\[
\leq \sigma_0^2 \| \beta_r \|^2 \| V_{\gamma}^{-4} \| \| z_{rk} \|^2 = O_P(n).
\]

Next, it is easy to show that

\[
\text{Var} \left[ C^{(i)} | Z \right] = \sigma_0^4 \text{trace} \left( M_i^2 \right) \leq \sigma_0^4 \| M_i \|^2 \cdot \max \{ n, \sum_{r=1}^{s} p_r \} \leq \frac{\sigma_0^4}{\gamma_i^2} \min \{ n, \sum_{r=1}^{s} p_r \} = O_P(n),
\]

and

\[
\text{Var} \left[ C^{(0)} | Z \right] = \sigma_0^4 \text{trace} \left( V_{\gamma}^{-4} \right) \leq \sigma_0^4 \| V_{\gamma}^{-4} \| \cdot \max \{ n, \sum_{r=1}^{s} p_r \} = O_P(n).
\]

By Chebyshev’s inequality and dominated convergence theorem, from (43), (46) and (47), we have for any \( \delta > 0 \) :

\[
\mathbb{P} \left\{ \left| \frac{1}{n} A^{(i)} - \mathbb{E} \left[ \frac{1}{n} A^{(i)} | Z \right] \right| > \delta \right\} \to 0 \text{ as } n \to \infty
\]

\[
\mathbb{P} \left\{ \left| \frac{1}{n} B^{(i)} - \mathbb{E} \left[ \frac{1}{n} B^{(i)} | Z \right] \right| > \delta \right\} \to 0 \text{ as } n \to \infty
\]

\[
\mathbb{P} \left\{ \left| \frac{1}{n} C^{(i)} - \mathbb{E} \left[ \frac{1}{n} C^{(i)} | Z \right] \right| > \delta \right\} \to 0 \text{ as } n \to \infty,
\]

which implies that

\[
\begin{align*}
n^{-1} A^{(i)} - \mathbb{E} \left[ n^{-1} A^{(i)} | Z \right] &= o_P(1) \\
n^{-1} B^{(i)} - \mathbb{E} \left[ n^{-1} B^{(i)} | Z \right] &= o_P(1) \\
n^{-1} C^{(i)} - \mathbb{E} \left[ n^{-1} C^{(i)} | Z \right] &= o_P(1)
\end{align*}
\]

33
Therefore,
\[
\frac{1}{n} y^\top V_{\gamma}^{-1} \left( \frac{1}{p_i} Z_i Z_i^\top \right) V_{\gamma}^{-1} y - \frac{1}{n} \mathbb{E} \left[ y^\top V_{\gamma}^{-1} \left( \frac{1}{p_i} Z_i Z_i^\top \right) V_{\gamma}^{-1} y | Z \right] \\
= \frac{1}{n} A^{(i)} - \mathbb{E} \left[ \frac{1}{n} A^{(i)} | Z \right] + \frac{2}{n} B^{(i)} - 2 \mathbb{E} \left[ \frac{1}{n} B^{(i)} | Z \right] + \frac{1}{n} C^{(i)} - \mathbb{E} \left[ \frac{1}{n} C^{(i)} | Z \right] = o_P(1).
\]

By a similar argument, we have
\[
\left\{ \begin{aligned}
n^{-1} A^{(0)} - \mathbb{E} \left[ n^{-1} A^{(0)} | Z \right] &= o_P(1) \\
n^{-1} B^{(0)} - \mathbb{E} \left[ n^{-1} B^{(0)} | Z \right] &= o_P(1) \\
n^{-1} C^{(0)} - \mathbb{E} \left[ n^{-1} C^{(0)} | Z \right] &= o_P(1)
\end{aligned} \right.
\]
and therefore
\[
\frac{1}{n} y^\top V_{\gamma}^{-2} y - \frac{1}{n} \mathbb{E} \left[ y^\top V_{\gamma}^{-2} y | Z \right] \\
= \frac{1}{n} A^{(0)} - \mathbb{E} \left[ \frac{1}{n} A^{(0)} | Z \right] + \frac{2}{n} B^{(0)} - 2 \mathbb{E} \left[ \frac{1}{n} B^{(0)} | Z \right] + \frac{1}{n} C^{(0)} - \mathbb{E} \left[ \frac{1}{n} C^{(0)} | Z \right] = o_P(1).
\]

Combining the above stochastic bounds and $\Delta^{(i)}(\gamma), \Delta^{(i)}(\gamma)$ defined in (36) and (37), there holds
\[
|\Delta^{(i)}(\gamma) - \Delta^{(i)}(\gamma)| \leq \left| \frac{1}{n} y^\top V_{\gamma}^{-1} \left( \frac{1}{p_i} Z_i Z_i^\top \right) V_{\gamma}^{-1} y - \frac{1}{n} \mathbb{E} \left[ y^\top V_{\gamma}^{-1} \left( \frac{1}{p_i} Z_i Z_i^\top \right) V_{\gamma}^{-1} y | Z \right] \right| \\
+ \left| \frac{1}{n} y^\top V_{\gamma}^{-2} y - \frac{1}{n} \mathbb{E} \left[ y^\top V_{\gamma}^{-2} y | Z \right] \right| = o_P(1).
\]

### 4.3.2 Control of $\Delta^{(i)}(\gamma) - \Delta^{(i)}(\gamma)$

Recall that $\Delta^{(i)}(\gamma)$ is given in (37). For $i = 1, \ldots, s$,
\[
\mathbb{E}[A^{(i)} | Z] = \sum_{r=1}^{s} \left( \sum_{k=1}^{p_r} \beta_{r}^2 z_{rk}^\top V_{\gamma}^{-1} \left( \frac{1}{p_i} Z_i Z_i^\top \right) V_{\gamma}^{-1} z_{rk} \right). 
\]

Since
\[
z_{ik}^\top V_{\gamma}^{-1} \left( \frac{1}{p_i} Z_i Z_i^\top \right) V_{\gamma}^{-1} z_{ik} = \frac{1}{\gamma_i} z_{ik}^\top V_{\gamma}^{-1} \left( V_{\gamma} - I_n - \sum_{r \neq i} \frac{\gamma_r}{p_r} Z_r Z_r^\top \right) V_{\gamma}^{-1} z_{ik},
\]

34
we have
\[
E[A^{(i)}|Z] = \frac{1}{\gamma_i} \sum_{k=1}^{p_i} \beta^2_{ik} z_{ik}^T V^{-1}_\gamma z_{ik} - \frac{1}{\gamma_i} \sum_{k=1}^{p_i} \beta^2_{ik} z_{ik}^T V^{-2}_\gamma z_{ik} - \sum_{r \neq i} \left( \frac{\gamma_r}{\gamma_i p_i} \sum_{k=1}^{p_i} \beta^2_{ik} z_{ik}^T V^{-1}_\gamma z_{ik} \right) + \sum_{r \neq i} \left( \frac{1}{p_i} \sum_{k=1}^{p_i} \beta^2_{rk} z_{rk}^T V^{-1}_\gamma z_{rk} \right).
\]

By (41) and (42), there holds that for \(i = 1, \ldots, s\),
\[
\max_{1 \leq k \leq p_i} \left| \frac{(z_{ik})^T V^{-1}_\gamma z_{ik}}{n} - \frac{1}{n} \frac{\text{trace}(V^{-1}_\gamma)}{n + \frac{2 \alpha}{p_i} \text{trace}(V^{-1}_\gamma)} \right| = O_P \left( \sqrt{\frac{\log n}{n}} \right),
\]
and
\[
\max_{1 \leq k \leq p_i} \left| \frac{(z_{ik})^T V^{-2}_\gamma z_{ik}}{n} - \frac{1}{n} \frac{\text{trace}(V^{-2}_\gamma)}{n + \frac{2 \alpha}{p_i} \text{trace}(V^{-1}_\gamma)^2} \right| = O_P \left( \sqrt{\frac{\log n}{n}} \right).
\]

Next, let’s calculate \(z_{ik}^T V^{-1}_\gamma Z_r V^{-1}_\gamma z_{ik}\). For \(1 \leq i, r \leq s, i \neq r\), and \(k = 1, \ldots, p_i\),
\[
z_{ik}^T V^{-1}_\gamma Z_r V^{-1}_\gamma z_{ik} = \sum_{j=1}^{p_r} (z_{ik}^T V^{-1}_\gamma z_{rj})^2.
\]

Recall that
\[
V^{-1}_\gamma = V^{-1}_{\gamma, -ik} - \frac{\gamma_i}{p_i} (1 + \frac{\gamma_i}{p_i} \rho_{ik})^{-1} V^{-1}_{\gamma, -ik} z_{ik} z_{ik}^T V^{-1}_{\gamma, -ik},
\]
which implies that
\[
z_{ik}^T V^{-1}_\gamma z_{rj} = (1 + \frac{\gamma_i}{p_i} \rho_{ik})^{-1} z_{ik}^T V^{-1}_{\gamma, -ik} z_{rj},
\]
and
\[
(z_{ik}^T V^{-1}_\gamma z_{rj})^2 = (1 + \frac{\gamma_i}{p_i} \rho_{ik})^{-2} z_{ik}^T V^{-1}_{\gamma, -ik} z_{rj} z_{rj}^T V^{-1}_{\gamma, -ik} z_{ik}.
\]

Since
\[
\lambda_{\text{max}} \left( V^{-1}_{\gamma, -ik} z_{rj} z_{rj}^T V^{-1}_{\gamma, -ik} \right)
\]
\[
= \lambda_{\text{max}} \left( V^{-1}_{\gamma, -ik} \left( V_{\gamma, -ik} - I_n - \frac{\gamma_i}{p_i} \sum_{l \neq k} z_{il} (z_{il})^T \right) \right.
\]
\[
- \sum_{q \neq i, r} \frac{\gamma_q}{p_q} z_{q} z_{q}^T - \frac{\gamma_r}{p_r} \sum_{m \neq j} z_{rm} (z_{rm})^T) V^{-1}_{\gamma, -ik} \right) \leq \lambda_{\text{max}} \left( V^{-1}_{\gamma, -ik} \right).
\]

35
we have
\[ \| V_{\gamma_{ik}}^{-1} z_{ij} V_{\gamma_{ik}}^{-1} \| \leq 1. \]

Then, the Hanson–Wright inequality gives
\[
\max_{1 \leq k \leq p_i} \max_{1 \leq j \leq p_r} \left| z_{ik}^T V_{\gamma_{ik}}^{-1} z_{ij} V_{\gamma_{ik}}^{-1} - \text{trace} \left( V_{\gamma_{ik}}^{-1} z_{ij} z_{kj} V_{\gamma_{ik}}^{-1} \right) \right| = O_P \left( \sqrt{n \log n} \right) \tag{53}
\]

with
\[ \text{trace} \left( V_{\gamma_{ik}}^{-1} z_{ij} z_{kj} V_{\gamma_{ik}}^{-1} \right) = z_{kj}^T V_{\gamma_{ik}}^{-2} z_{kj}. \]

It is easy to show that
\[
\left| \text{trace}(V_{\gamma}^{-2}) - \text{trace}(V_{\gamma_{ik}}^{-1} z_{ij} z_{kj}) \right| \\
\leq \left| \text{trace}(V_{\gamma}^{-2}) - \text{trace}(V_{\gamma_{ik}}^{-1}) \right| + \left| \text{trace}(V_{\gamma_{ik}}^{-1}) - \text{trace}(V_{\gamma_{ik}}^{-1}) \right|
\leq \frac{2\gamma_i}{p_i} \left( 1 + \frac{\gamma_i}{p_i} \rho_{ik} \right)^{-1} \rho_{ik} + \left( \frac{\gamma_i}{p_i} \right)^2 \left( 1 + \frac{\gamma_i}{p_i} \rho_{ik} \right)^{-2} \rho_{ik}^2
+ \frac{2\gamma_r}{p_r} \left( 1 + \frac{\gamma_r}{p_r} \rho_{ik,kr} \right)^{-1} \rho_{ik,kr} + \left( \frac{\gamma_r}{p_r} \right)^2 \left( 1 + \frac{\gamma_r}{p_r} \rho_{ik,kr} \right)^{-2} \rho_{ik,kr}^2 < 6,
\]

where \( \rho_{ik,kr} := (z_{kj})^T (V_{\gamma_{ik}}^{-1} z_{kj})^{-1} z_{kj}. \) Then, as similar to the case of \( \phi_{ik} \), we have
\[
\max_{1 \leq k \leq p_i} \left| z_{ik}^T V_{\gamma_{ik}}^{-2} z_{ij} V_{\gamma_{ik}}^{-1} - \text{trace}(V_{\gamma}^{-2}) \right| = O_P \left( \sqrt{n \log n} \right),
\]

and
\[
\max_{1 \leq k \leq p_i} \max_{1 \leq j \leq p_r} \left| \frac{z_{kj}^T V_{\gamma_{ik}}^{-1} z_{rk} V_{\gamma_{ik}}^{-1} z_{ki}}{n} - \frac{1}{n} \frac{\text{trace}(V_{\gamma}^{-2})}{\left( 1 + \frac{2\gamma_i}{p_i} \text{trace}(V_{\gamma}^{-1}) \right)^2} \right| = O_P \left( \sqrt{\frac{\log n}{n}} \right).\]

Combine with (53), we have
\[
\max_{1 \leq k \leq p_i} \max_{1 \leq j \leq p_r} \left| \frac{z_{ik}^T V_{\gamma_{ik}}^{-1} z_{ij} z_{kj} V_{\gamma_{ik}}^{-1} z_{ki}}{n} - \frac{1}{n} \frac{\text{trace}(V_{\gamma}^{-2})}{\left( 1 + \frac{2\gamma_i}{p_i} \text{trace}(V_{\gamma}^{-1}) \right)^2} \right| = O_P \left( \sqrt{\frac{\log n}{n}} \right).\]

We are now ready to plug the above approximation into (52) and then (51) to find a
neat approximation of $z_{ik}^\top V_\gamma^{-1} Z_r Z_r^\top V_\gamma^{-1} z_{ik}$. As before, we can obtain

$$
\max_{1 \leq k \leq p_i} \left| \frac{1 + \frac{\gamma_i}{p_i} \text{trace}(V_\gamma^{-1})}{p_i} - \left(1 + \frac{\gamma_i}{p_i} \rho_{ik}\right)^{-2} \right|
\leq \max_{1 \leq k \leq p_i} \frac{\gamma_i}{p_i} \left(\rho_{ik} - \text{trace}(V_\gamma^{-1})\right) \left(1 + \frac{\gamma_i}{p_i} \rho_{ik}\right)^{-1}
\leq \max_{1 \leq k \leq p_i} \frac{\gamma_i}{p_i} \rho_{ik} - \text{trace}(V_\gamma^{-1}) \left(1 + \frac{\gamma_i}{p_i} \rho_{ik}\right)^{-1} \left(1 + \frac{\gamma_i}{p_i} \rho_{ik}\right)^{-1}
= O_P \left(\sqrt{\frac{\log n}{n}}\right),
$$

Then, (52) gives

$$
\max_{1 \leq k \leq p_i, 1 \leq j \leq p_r} \left| \frac{(z_{ik}^\top V_\gamma^{-1} z_{ij})^2}{n} - \frac{1}{n} \frac{\text{trace}(V_\gamma^{-2})}{\left(1 + \frac{\gamma_i}{p_i} \text{trace}(V_\gamma^{-1})\right)^2} \right|
\leq \max_{1 \leq k \leq p_i, 1 \leq j \leq p_r} \left| \frac{z_{ik}^\top V_\gamma^{-1} z_{ij} n}{\left(1 + \frac{\gamma_i}{p_i} \rho_{ik}\right)^2} - \frac{1}{n} \frac{\text{trace}(V_\gamma^{-2})}{\left(1 + \frac{\gamma_i}{p_i} \rho_{ik}\right)^2} \right|
\leq \max_{1 \leq k \leq p_i, 1 \leq j \leq p_r} \left| \frac{1}{n} \frac{\text{trace}(V_\gamma^{-2})}{\left(1 + \frac{\gamma_i}{p_i} \rho_{ik}\right)^2} \right|
+ \max_{1 \leq k \leq p_i, 1 \leq j \leq p_r} \left| \frac{1}{n} \frac{\text{trace}(V_\gamma^{-2})}{\left(1 + \frac{\gamma_i}{p_i} \rho_{ik}\right)^2} \right|
= O_P \left(\sqrt{\frac{\log n}{n}}\right),
$$

37
where we have used the fact that \( \text{trace}(V^{-2}) \leq n \). Then, (51) gives

\[
\max_{1 \leq k \leq p_i} \left| \frac{z_{ik}^\top V^{-1} \frac{1}{p_i} Z_i Z_i^\top V^{-1} z_{ik}}{n} - \frac{\text{trace}(V^{-2})}{n \left( 1 + \frac{2n}{p_i} \text{trace}(V^{-1}) \right)^2} \right| \leq O_P \left( \sqrt{\frac{\log n}{n}} \right).
\]

The asymptotic approximation for \( z_{rk}^\top V^{-1} Z_r Z_i^\top V^{-1} z_{rk} \) is similar.

We are now ready to study (49). The idea is the same as what has been shown in the case of standard linear model, so we skip most of the details. For example, the asymptotic approximation (50) implies both

\[
\frac{1}{n} \frac{\text{trace}(V_{\gamma}^{-1})}{n \gamma_i} - \frac{1}{n} \frac{\text{trace}(V_{\gamma}^{-2})}{n \left( 1 + \frac{2n}{p_i} \text{trace}(V_{\gamma}^{-1}) \right)^2} = O_P \left( \sqrt{\frac{\log n}{n}} \right),
\]

and

\[
\frac{1}{n} \frac{\text{trace}(V_{\gamma}^{-1})}{n \gamma_i} - \frac{1}{n} \frac{\text{trace}(V_{\gamma}^{-1} Z_i Z_i^\top)}{n \left( 1 + \frac{2n}{p_i} \text{trace}(V_{\gamma}^{-1}) \right)^2} = O_P \left( \sqrt{\frac{\log n}{n}} \right).
\]

Putting them together, we have

\[
\left| \frac{1}{n} \frac{\||\beta_i\||^2}{p_i \gamma_i} \text{trace} \left( V_{\gamma}^{-1} Z_i Z_i^\top \right) - \frac{1}{n} \frac{\text{trace}(V_{\gamma}^{-1} Z_i Z_i^\top)}{n \gamma_i} \sum_{k=1}^{p_i} \beta_{ik}^2 z_{ik} V_{\gamma}^{-1} z_{ik} \right| = O_P \left( \sqrt{\frac{\log n}{n}} \right).
\]

Similarly, we have

\[
\left| \frac{1}{n} \frac{\||\beta_i\||^2}{p_i \gamma_i} \text{trace} \left( V_{\gamma}^{-2} Z_i Z_i^\top \right) - \frac{1}{n} \frac{\text{trace}(V_{\gamma}^{-2} Z_i Z_i^\top)}{n \gamma_i} \sum_{k=1}^{p_i} \beta_{ik}^2 z_{ik} V_{\gamma}^{-2} z_{ik} \right| = O_P \left( \sqrt{\frac{\log n}{n}} \right),
\]

\[
\left| \sum_{r \neq i} \left( \frac{\gamma_r}{n \gamma_i p_r} \sum_{k=1}^{p_i} \beta_{ik}^2 z_{ik} V_{\gamma}^{-1} Z_r Z_r^\top V_{\gamma}^{-1} z_{ik} \right) - \sum_{r \neq i} \left( \frac{\||\beta_i\||^2}{n \gamma_i} \text{trace} \left( V_{\gamma}^{-1} \frac{1}{p_r} Z_r Z_r^\top V_{\gamma}^{-1} \frac{1}{p_i} Z_i Z_i^\top \right) \right) \right| = O_P \left( \sqrt{\frac{\log n}{n}} \right),
\]

and

\[
\left| \sum_{r \neq i} \left( \frac{1}{n p_i} \sum_{k=1}^{p_r} \beta_{rk}^2 z_{rk} V_{\gamma}^{-1} Z_i Z_i^\top V_{\gamma}^{-1} z_{rk} \right) - \sum_{r \neq i} \left( \frac{\||\beta_i\||^2}{n} \text{trace} \left( V_{\gamma}^{-1} \frac{1}{p_r} Z_r Z_r^\top V_{\gamma}^{-1} \frac{1}{p_i} Z_i Z_i^\top \right) \right) \right| = O_P \left( \sqrt{\frac{\log n}{n}} \right).
\]
Putting these bounds back to (49), and replacing \( \| \beta_i \| \) with \( \sigma_0^2 \gamma_0 \), we can show that
\[
\left| \frac{1}{n} \mathbb{E}[A^{(i)}|Z] - \frac{1}{n} \left( \frac{\sigma_0^2 \gamma_0}{\gamma_i} \right) \text{trace} \left( \mathbf{V}_{\gamma}^{-1} \frac{1}{p_i} \mathbf{Z}_i \mathbf{Z}_i^\top \right) - \frac{\sigma_0^2 \gamma_0}{\gamma_i} \text{trace} \left( \mathbf{V}_{\gamma}^{-2} \frac{1}{p_i} \mathbf{Z}_i \mathbf{Z}_i^\top \right) \right| = O_P \left( \sqrt{\frac{\log n}{n}} \right). \tag{54}
\]

Similarly, for \( i = 1, \ldots, s \),
\[
\mathbb{E}[A^{(0)}|\mathbf{Z}] = \sum_{r=1}^{s} \left( \sum_{k=1}^{p_r} \beta_{r,k}^2 \mathbf{z}_{r,k} \mathbf{V}_{\gamma}^{-2} \mathbf{z}_{r,k} \right),
\]
and we can have
\[
\left| \frac{1}{n} \mathbb{E}[A^{(0)}|\mathbf{Z}] - \frac{1}{n} \sum_{r=1}^{s} \| \beta_r \|^2 \text{trace} \left( \mathbf{V}_{\gamma}^{-2} \mathbf{Z}_r \mathbf{Z}_r^\top \right) \right| = O_P \left( \sqrt{\frac{\log n}{n}} \right).
\]

Since
\[
\frac{\| \beta_r \|^2}{p_r \sigma_0^2} \text{trace} \left( \mathbf{V}_{\gamma}^{-2} \mathbf{Z}_r \mathbf{Z}_r^\top \right) = \frac{\gamma_0}{\gamma_i} \text{trace} \left( \mathbf{V}_{\gamma}^{-1} \left( \frac{1}{p_i} \mathbf{Z}_i \mathbf{Z}_i^\top \right) \mathbf{V}_{\gamma}^{-1} \right) + \sum_{r \neq i} \gamma_0 \text{trace} \left( \mathbf{V}_{\gamma}^{-1} \left( \frac{1}{p_r} \mathbf{Z}_r \mathbf{Z}_r^\top \right) \mathbf{V}_{\gamma}^{-1} \right)
\]
\[
\quad = \frac{\gamma_0}{\gamma_i} \text{trace} \left( \frac{1}{\gamma_i} \mathbf{V}_{\gamma}^{-1} \left( \mathbf{V}_{\gamma} - \mathbf{I}_n - \sum_{r \neq i} \frac{\gamma_r}{p_r} \mathbf{Z}_r \mathbf{Z}_r^\top \right) \mathbf{V}_{\gamma}^{-1} \right) + \sum_{r \neq i} \gamma_0 \text{trace} \left( \mathbf{V}_{\gamma}^{-1} \left( \frac{1}{p_r} \mathbf{Z}_r \mathbf{Z}_r^\top \right) \mathbf{V}_{\gamma}^{-1} \right)
\]
\[
\quad = \frac{\gamma_0}{\gamma_i} \text{trace} \left( \mathbf{V}_{\gamma}^{-1} \right) - \frac{\gamma_0}{\gamma_i} \text{trace} \left( \mathbf{V}_{\gamma}^{-2} \right) + \sum_{r \neq i} \gamma_r \left( \frac{\gamma_0}{\gamma_r} - \frac{\gamma_0}{\gamma_i} \right) \text{trace} \left( \mathbf{V}_{\gamma}^{-2} \left( \frac{1}{p_r} \mathbf{Z}_r \mathbf{Z}_r^\top \right) \right),
\]
we have
\[
\left| \frac{1}{n} \mathbb{E}[A^{(0)}|\mathbf{Z}] - \frac{1}{n} \left( \frac{\sigma_0^2 \gamma_0}{\gamma_i} \right) \text{trace} \left( \mathbf{V}_{\gamma}^{-1} \right) - \frac{\sigma_0^2 \gamma_0}{\gamma_i} \text{trace} \left( \mathbf{V}_{\gamma}^{-2} \right) \right| + \sum_{r \neq i} \sigma_0^2 \gamma_r \left( \frac{\gamma_0}{\gamma_r} - \frac{\gamma_0}{\gamma_i} \right) \text{trace} \left( \mathbf{V}_{\gamma}^{-2} \frac{1}{p_r} \mathbf{Z}_r \mathbf{Z}_r^\top \right) \right| = O_P \left( \sqrt{\frac{\log n}{n}} \right), \tag{55}
\]

Combining \( \mathbb{E}[B^{(i)}|\mathbf{Z}] = 0 \) and \( \mathbb{E}[C^{(i)}|\mathbf{Z}] = \sigma_0^2 \text{trace} \left( \mathbf{V}_{\gamma}^{-1} \frac{1}{p_i} \mathbf{Z}_i \mathbf{Z}_i^\top \mathbf{V}_{\gamma}^{-1} \right) \) with (54), there
holds

\[
\frac{1}{n} \mathbb{E} \left[ y^\top V_\gamma^{-1} \left( \frac{1}{p_i} Z_i Z_i^\top \right) V_\gamma^{-1} y \bigg] \mathbb{E} \left[ y^\top V_\gamma^{-2} y \bigg] - \frac{\sigma_0^2}{n} \left( \frac{\gamma_{0i}}{\gamma_i} \right) \left( \frac{\gamma_{0i}}{\gamma_i} \right) \frac{\text{trace} \left( V_\gamma^{-1} \frac{1}{p_i} Z_i Z_i^\top \right)}{\text{trace} \left( V_\gamma^{-1} \frac{1}{p_i} Z_i Z_i^\top \right)}
\]

\[
+ \left( 1 - \frac{\gamma_{0i}}{\gamma_i} \right) \text{trace} \left( V_\gamma^{-2} \frac{1}{p_i} Z_i Z_i^\top \right) + \sum_{r \neq i} \gamma_r \left( \frac{\gamma_{0r}}{\gamma_r} - \frac{\gamma_{0i}}{\gamma_i} \right) \text{trace} \left( V_\gamma^{-2} \frac{1}{p_r} Z_r Z_r^\top \right) \right) = O_P \left( \sqrt{\frac{\log n}{n}} \right).
\]

Similarly, by (55) and \( \mathbb{E}[B^{(0)}] = 0 \) and \( \mathbb{E}[C^{(0)}] = \sigma_0^2 \text{trace} \left( V_\gamma^{-2} \right) \), we can get

\[
\frac{1}{n} \mathbb{E} \left[ y^\top V_\gamma^{-2} y \bigg] - \frac{\sigma_0^2}{n} \left( \frac{\gamma_{0i}}{\gamma_i} \right) \left( \frac{\gamma_{0i}}{\gamma_i} \right) \frac{\text{trace} \left( V_\gamma^{-1} \right)}{\text{trace} \left( V_\gamma^{-1} \right)}
\]

\[
+ \sum_{r \neq i} \gamma_r \left( \frac{\gamma_{0r}}{\gamma_r} - \frac{\gamma_{0i}}{\gamma_i} \right) \text{trace} \left( V_\gamma^{-2} \frac{1}{p_r} Z_r Z_r^\top \right) \right) = O_P \left( \sqrt{\frac{\log n}{n}} \right).
\]

Recall that

\[
\Delta^{(i)}_{ss} (\gamma) = \sigma_0^2 \left( 1 - \frac{\gamma_{0i}}{\gamma_i} \right) \frac{\text{trace} \left( V_\gamma^{-2} \frac{1}{p_i} Z_i Z_i^\top \right)}{\text{trace} \left( V_\gamma^{-1} \frac{1}{p_i} Z_i Z_i^\top \right)} - \frac{\sigma_0^2}{n} \left( \frac{\gamma_{0i}}{\gamma_i} \right) \left( \frac{\gamma_{0i}}{\gamma_i} \right) \frac{\text{trace} \left( V_\gamma^{-1} \frac{1}{p_i} Z_i Z_i^\top \right)}{\text{trace} \left( V_\gamma^{-1} \frac{1}{p_i} Z_i Z_i^\top \right)}
\]

\[
+ \sigma_0^2 \sum_{r \neq i} \gamma_r \left( \frac{\gamma_{0r}}{\gamma_r} - \frac{\gamma_{0i}}{\gamma_i} \right) \frac{\text{trace} \left( V_\gamma^{-1} \frac{1}{p_r} Z_r Z_r^\top \right)}{\text{trace} \left( V_\gamma^{-2} \frac{1}{p_r} Z_r Z_r^\top \right)} \right),
\]

and

\[
\Delta^{(i)} (\gamma) = \frac{1}{n} \mathbb{E} \left[ y^\top V_\gamma^{-1} \left( \frac{1}{p_i} Z_i Z_i^\top \right) V_\gamma^{-1} y \bigg] - \frac{1}{n} \mathbb{E} \left[ y^\top V_\gamma^{-2} y \bigg].
\]

Note that

\[
\frac{1}{n} \text{trace} \left( V_\gamma^{-1} \frac{1}{p_i} Z_i Z_i^\top \right) \leq \frac{1}{n} \| V_\gamma^{-1} \| \text{trace} \left( \frac{1}{p_i} Z_i Z_i^\top \right) \leq \frac{1}{n} \max_{1 \leq k \leq p_i} \| z_{ik} \| = O_P(1)
\]

and

\[
\frac{1}{n} \text{trace} \left( V_\gamma^{-1} \right) \leq \frac{1}{n} \| V_\gamma^{-1} \| \min \{ n_i \sum_{r=1}^s p_s \} = O(1), \quad \frac{1}{n} \text{trace} \left( V_\gamma^{-2} \right) = O(1).
\]

Combining all these stochastic order above, we have

\[
|\Delta^{(i)} (\gamma) - \Delta^{(i)}_{ss} (\gamma)| = O_P \left( \sqrt{\frac{\log n}{n}} \right).
\]
4.3.3 Completing the proof of Theorem 2.2

From what we have discussed above, there holds that $|\Delta^{(i)}(\gamma) - \Delta_*^{(i)}(\gamma)| \xrightarrow{P} 0$ and $|\Delta_*^{(i)}(\gamma) - \Delta_*^{(i)}(\gamma)| \xrightarrow{P} 0$. Thus $|\Delta^{(i)}(\gamma) - \Delta_*^{(i)}(\gamma)| \xrightarrow{P} 0$. The fact $\Delta_*^{(i)}(\gamma_0) = 0$ implies that the likelihood equations on the SNR parameters defined in (12) satisfy $\Delta^{(i)}(\gamma_0) \xrightarrow{P} 0$ for $i = 1, \ldots, s$, as $n \to \infty$.

5 Discussion

This paper is concerning estimation of signal-to-noise ratios and noise variances in linear models via linear random effects model based maximum likelihood estimation. In particular, we have conducted model misspecification analysis where the true model only has fixed effects. Our results provide conditions on the design matrices under which random effects MLE lead to consistent estimation, where the dimension is allowed to be greater than the sample size. Our model misspecification analysis also extends to the high-dimensional linear models with group features for group SNRs estimation.

For future work, a strong assumption in Theorem 2.1 is that the entries are assumed to be independent, which leads to isotropic population covariance matrix. This is a common assumption in misspecification analysis of linear random effects models (Jiang et al., 2016; Dicker and Erdogdu, 2017, 2016), but it seems to be too strong since it implies that the variables are exchangeable in some sense. One future research direction is to relax this isotropic structure in the design matrix. Another key assumption in Theorem 2.1 is that the subgaussian entries are assumed to be symmetric. We make this assumption in order to use the trick of Rademacher sequences introduced in Section 2.3. However, our numerical results in Section 3.1 suggest that this assumption may be a mathematical artifact. Also, the assumption of symmetry is usually violated in real applications, such as GWAS. It is both interesting and significant to study whether this assumption can be relaxed to simply mean-zero.

In terms of the asymptotic analysis in Theorem 2.1, we only discuss the existence but not the uniqueness of solutions of the likelihood equation (5). In fact, the asymptotic analysis of $\Delta(\gamma)$ suggests that it may have a unique root $\hat{\gamma}_n$ that converges to $\gamma_0$. We leave the investigation of uniqueness for future work. Asymptotic normality of random effects MLE has been introduced in existing misspecification analysis (Jiang et al., 2016; Dicker and Erdogdu, 2016). However, such analysis is technically complicated under the settings of Theorem 2.1. It would be interesting to establish the asymptotic normality beyond the consistency analysis given in Theorem 2.1.

One interesting extension of Theorem 2.1 is the linear model with heteroscedastic noise, in which $\text{Var}(\varepsilon_i) = \sigma^2_{0i}$. For simplicity, we assume that $\frac{1}{n} \sum_{i=1}^n \sigma^2_{0i} = \sigma^2_0$ is fixed in $n$. In this case, will the likelihood equation (5) still yield a consistent estimator of the true SNR value defined as $\gamma_0 = \|\beta\|^2/\sigma^2_0$? Here we give some idea on how to modify the previous analysis under the additional assumption that the elements of $Z$ are i.i.d. (recalling that in Theorem 2.1 the elements of the design matrix are not assumed to be identically distributed). Due to the heteroscedasticity of the noise, the terms $\sigma^2_0 \text{trace}(V_{\gamma}^{-1})$ and $\sigma^2_0 \text{trace}(V_{\gamma}^{-2})$ should be replaced with $\text{trace}(D_n V_{\gamma}^{-1})$ and $\text{trace}(D_n V_{\gamma}^{-2})$, where $D_n = \text{diag}(\sigma^2_{01}, \ldots, \sigma^2_{0n})$. By
Theorem 1 of Rubio and Mestre (2011), which is a generalized Marchenko-Pastur theorem, there holds
\[
\frac{1}{n} \text{trace} \left( D_n V_\gamma^{-1} \right) \xrightarrow{a.s.} \sigma_0^2 \int_{b_+}^{b_-} \frac{f_\tau(x)}{1+\gamma x} \, dx
\]
By Lemma 2.14 in Bai and Silverstein (2010), taking derivatives with respect to \( \lambda \) on both sides, we have
\[
\frac{1}{n} \text{trace} \left( D_n V_\gamma^{-2} \right) \xrightarrow{a.s.} \sigma_0^2 \int_{b_+}^{b_-} \frac{f_\tau(x)}{(1+\gamma x)^2} \, dx.
\]
Then the asymptotic limit of \( \Delta_{ss}^*(\gamma) \) can be established as before, so the argument to prove Theorem 2.1 can be extended to the case of heteroscedastic noise. The formalization of the above argument still requires some meticulous probabilistic analysis, and we leave this for future work.

As to the linear model (8) in which the design matrix is partitioned according to feature groups, we have only discussed the likelihood equations (12) in Theorem 2.2, and show that they hold asymptotically at the true SNR values \( \gamma_0 \). Theorem 2.2 does not imply the existence of MLE \( (\hat{\sigma}_0^2, \hat{\sigma}_{\alpha_1}^2, \ldots, \hat{\sigma}_{\alpha_s}^2) \) as local maximum to the log likelihood function (9) and its consistency to \( (\sigma_0^2, \|\beta_1\|^2, \ldots, \|\beta_s\|^2) \). A remaining question is to fill this gap.

One idea to show the existence and consistency of MLE is to investigate the likelihood function directly rather than the likelihood equations for the SNR parameters. In fact, by introducing a Rademacher sequence as we have discussed in Section 2.3, we can obtain the following approximation
\[
\frac{1}{n} \ell(\sigma_\varepsilon^2, \sigma_{\alpha_1}^2, \ldots, \sigma_{\alpha_s}^2) \approx \frac{1}{n} \ell_{ss}(\sigma_\varepsilon^2, \sigma_{\alpha_1}^2, \ldots, \sigma_{\alpha_s}^2) := -\frac{1}{2n} \log \det(\sigma_\varepsilon^2 V_\gamma) - \frac{1}{2n} \frac{1}{\sigma_\varepsilon^2} \left( \sum_{i=1}^s \|\beta_i\|^2 \text{trace}(V_\gamma^{-2} \frac{1}{P_i} Z_i Z_i^\top) + \sigma_0^2 \text{trace}(V_\gamma^{-2}) \right).
\]
Under certain assumptions on \( \beta \) as well as the distribution of \( \varepsilon \), the above approximation may hold uniformly over a domain of \( (\sigma_\varepsilon^2, \gamma) \) by applying ideas similar to the uniform Hanson-Wright inequality introduced in Dicker and Erdogdu (2017). The next step is to show that the true value of parameters \( (\sigma_0^2, \gamma_0) \) is a local maximum of \( \ell_{ss}(\sigma_\varepsilon^2, \gamma) \). Calculation and analysis of Taylor expansion of \( \ell_{ss}(\sigma_\varepsilon^2, \gamma) \) around \( (\sigma_0^2, \gamma_0) \) is needed, and replacing the standard Hanson-Wright inequality with the uniform version in the leave-one-out analysis still requires novel ideas and meticulous analysis. Nevertheless, we leave this asymptotic analysis of MLE in the case of misspecification for future work.
