SCATTERING FOR SCHRÖDINGER OPERATORS WITH POTENTIALS CONCENTRATED NEAR A SUBSPACE

ADAM BLACK AND TAL MALINOVITCH

Abstract. We study the scattering properties of Schrödinger operators with bounded potentials concentrated near a subspace of $\mathbb{R}^d$. For such operators, we show the existence of scattering states and characterize their orthogonal complement as a set of surface states, which consists of states that are confined to the subspace (such as pure point states) and states that escape it at a sublinear rate, in a suitable sense. Our proof uses a novel interpretation of the Enss method [11] in order to obtain a dynamical characterisation of the orthogonal complement of the scattering states.

1. Introduction

In this paper, we study the scattering properties of Schrödinger operators with potentials concentrated near a subspace of \( \mathbb{R}^d \). This is one of many models of a quantum particle interacting with a surface. For such operators, we show the existence of scattering states and characterize their orthogonal complement as a set of surface states, which consists of states that are confined to the subspace (such as pure point states) and states that escape it at a sublinear rate, in a suitable sense.

1.1. Motivation and prior work. Our work is motivated by the vast literature studying the scattering theory of Schrödinger operators with potentials that decay at infinity. Typically, these are self-adjoint operators on \( \mathcal{H} = L^2(\mathbb{R}^d) \) of the form

\[
H = H_0 + V
\]

where \( H_0 = -\Delta \) and \( V \), the potential, is a real-valued multiplication operator. For short range potentials, that is, those with sufficiently fast decay, one is interested in showing that the wave operators

\[
\Omega^\pm = \underset{t \to \mp \infty}{\text{s-lim}} e^{itH} e^{-itH_0}
\]

exist on all of \( \mathcal{H} \) and are asymptotically complete in the sense that their range is equal to the continuous subspace of \( H \). Intuitively, states in the range of \( \Omega^\pm \) behave like free particles as \( t \to \mp \infty \). We make no attempt to comprehensively review the multitude of results concerning which assumptions on \( V \) yield asymptotic completeness. However, we mention the seminal work of Agmon [1] (and the references therein), in which asymptotic completeness is shown for \( V \) satisfying, for instance,

\[
V(x) = O(|x|^{1+\epsilon}) \text{ as } x \to \infty
\]

Our paper is based on the work on Enss [11] showing asymptotic completeness for potentials satisfying a short range condition, which for a bounded potentials can be written as

\[
\|V \chi_{B^c_r}\| \in L^1(r)
\]

where \( \chi \) denotes an indicator function and \( B^c_r \) is the complement of the ball of radius \( r \) in \( \mathbb{R}^d \).

In a related direction, many authors have investigated the scattering theory of Schrödinger operators with anisotropic potentials that have different behavior in different coordinate directions (see, for example, [6,3,7,23]). Building on one-dimensional results of Carmona [3], Davies and Simon [7] investigated potentials \( V \) that are periodic in the coordinate directions \( \{x_1, \ldots, x_{d-1}\} \) but with different spatial asymptotics as \( x_d \) goes to plus or minus infinity. They showed that in this setting, the absolutely continuous subspace of \( H \) decomposes into pieces that, under the evolution of \( H \), move to \( \pm \infty \) in the \( x_d \) coordinate and surface states that are localized near the hypersurface \( \{x_d = 0\} \) for all time. We review this result more thoroughly in Section 6 but for now we note that even if \( V \) goes to 0 rapidly as \( x_d \to \pm \infty \), there may still exist surface states in the ac subspace of \( H \). Furthermore, a state in the range of \( \Omega^\pm \) cannot be localized near a hypersurface for all time (see Section 5.3) so the presence of ac surface states may be thought of as an obstruction to asymptotic completeness.

In view of the circle of ideas recalled above, one may naturally ask what can be said about the scattering theory of potentials that decay at infinity but only in some coordinate directions. By this, we mean a potential \( V \) that is concentrated (in a sense to be specified
later) near the surface \( \{ x \in \mathbb{R}^d \mid x_{k+1} = \cdots x_d = 0 \} \) for some \( 1 \leq k < d \). The aforementioned class of examples shows that one cannot expect asymptotic completeness in this setting because some states may undergo transport along the surface. However, one has the following very plausible physical picture: a state which moves away from the surface as time evolves should feel the influence of the potential less and less, so it should behave asymptotically like a free particle and therefore be in the range of the wave operator. This suggests that there is a dichotomy between states that remain near the surface and those that are asymptotically free irrespective of the precise nature of \( V \). So, one should really ask: for \( V \) as above, is the orthogonal complement of \( \text{Ran} \Omega^\pm \) given by the space of surface states? The present paper is an affirmative answer to this question.

Before stating our results, let us mention that many authors have studied the spectral and scattering theory of surface potentials due in part to their physical importance. We refer the reader to \([9, 13, 14, 15, 17, 18, 19]\) for some idea of the questions that have been investigated for surface models. In these papers and others, the authors are usually interested in surface potentials with some additional structure. For instance, among other examples, Davies and Simon \([7]\) consider a partially periodic potential so that they may leverage symmetry. Other authors investigate random surface potentials \([9, 14]\) or a (possibly discrete) half-space model with some boundary condition (such as \([13, 17, 18, 19]\)). In many of these cases, additional structure allows for a better description of the surface subspace than one might hope for in full generality, either by showing it is trivial \([17]\) or by giving a more restrictive definition \([7]\). In this paper, we make significantly weaker assumptions on \( V \) - only that it is bounded and has the right decay away from the surface - at the price of a more inclusive description of the surface states. Therefore, many of these prior models fall within the purview of our theorem.

1.2. Model and results. We consider a self-adjoint operator \( H \) on \( \mathcal{H} = L^2(\mathbb{R}^d) \) of the form (1.1.1), where \( V \) is a real-valued bounded potential such that

\[
\text{supp } V \subset \{ x \in \mathbb{R}^d \mid \| (x_{k+1}, \ldots, x_d) \| \leq r_0 \} =: S^k_{r_0} \\
\sup_{x \in \mathbb{R}^d} |V(x)| = M < \infty
\]

for some \( r_0 > 0 \) and \( 1 \leq k < d \). Since \( k \) is fixed throughout the paper, we will suppress it in the notation. Let us define the following family of subsets of \( \mathbb{R}^d \)

\[
A_{n,m} = \{ x \mid m\|x^\perp\| > \|x^\parallel\| + mn \}
\]

where \( m := \cot(\gamma) > 1 \), for \( \gamma \) some angle between 0 and \( \frac{\pi}{4} \). For \( k = 1 \), \( A^c_{n,m} \) is the union of the cone of aperture of \( 2\gamma \) with \( e_1 \) direction shifted by \( mn \) along \( -e_1 \), and the cone of aperture \( 2\gamma \) with \( -e_1 \) direction shifted by \( mn \) along \( e_1 \). See Figure 1.

We define the space of surface states to be

\[
\mathcal{H}_{\text{sur}} = \{ \psi \in \mathcal{H} \mid \forall m > 1, \forall v > 0, \limsup_{t \to \infty} \| \chi_{A_{v,t,m}} e^{-itH} \psi \| = \| \psi \| \}
\]

Our main theorem is that

**Theorem 1.1.**

(i) (Existence) For all \( \psi \in \mathcal{H} \) the limits \( \Omega^\pm \psi \) exist. Furthermore, \( \sigma(H_0) \subset \sigma_{\text{ac}}(H) \).

(ii) (Completeness) We have

\[
\mathcal{H} = \mathcal{H}_{\text{sur}} \oplus \text{Ran}(\Omega^-)
\]
The existence result may essentially be found in [15], though we supply our own proof. See also Chapter 2, Section 10 of [20] for a related existence theorem.

**Remark.** The above theorem may be easily generalized to allow $V$ satisfying
\[ \| \chi_{\mathbb{R}^d} V \|_{op} \in L^1_R \sup_{x \in \mathbb{R}^d} |V(x)| = M < \infty \]
that is, potentials $V$ which decay perpendicular to the surface in a short range way. Broadly speaking, the $L^1$ condition enters in a similar way as in [11]. For simplicity of presentation we have restricted to the case where $\chi_{\mathbb{R}^d} V$ is in fact 0 for $R$ large enough, but we have explained how to adapt our proof to this generalization in Appendix B.

**Remark.** The definition of $\mathcal{H}_{\text{sur}}$ is closely related to the notion of a *minimal velocity estimate* as exhibited in [16]. A typical estimate of this type for a state $\psi$ might be of the form
\[ \| \chi_{B^v} e^{-itH} \psi \| \leq C t^{-\ell} \| \psi \| \]
for some $\ell > 0$ and all $v$ less than some $v_0$. Such an estimate usually results from a Mourre estimate on some energy interval, in the presence of which one already expects asymptotic completeness (for a self-contained exposition of these ideas, see Chapter 4 of [10]). An easy corollary of our Theorem 1.1 is that a state $\psi$ is a scattering state if it satisfies a minimal velocity estimate relative to the region $A_{vt,m}$, i.e., if for some $m > 1$ and $v > 0$
\[ \lim_{t \to \infty} \| \chi_{A_{vt,m}} e^{-itH} \psi \| = 0 \]
Thus, our theorem provides a dynamical criterion for asymptotic completeness, which may be verified via commutator methods.

1.3. **Methodology: the Enss Method of scattering.** We rely on the Enss method of scattering originally developed in [11], whose geometric flavor is well-suited to our problem. The Enss method realizes the physical intuition developed above: if $V$ satisfies (1.1.2), a state which moves away from the origin under the $H$ evolution is asymptotically free. In Enns’ original argument, one fixes a state $\psi$ in the absolutely continuous subspace of $H$ and finds a sequence of times $t_n \to \infty$ for which $\psi_n = e^{-it_n H} \psi$ satisfies
\[ \| \chi_{B^v} \psi_n \| \to 0 \]
so that $\psi_n$ is moving away from the origin. This is possible for $V$ a relatively bounded perturbation of $H_0$ with relative bound less than 1 by the celebrated RAGE theorem [2, 24], which says that a state $\psi$ in the continuous subspace escapes every compact set $K$ in a time mean sense:
\[ \lim_{T \to \infty} \frac{1}{T} \int_0^T \| \chi_K \psi \| \, dt = 0 \]
Along the sequence $\{t_n\}_{n=1}^\infty$, one then performs a *phase space decomposition* of $\psi_n$ into incoming and outgoing pieces:
\[ \psi_n = \psi_{n,\text{in}} + \psi_{n,\text{out}} + o(1) \]
Both $\psi_{n,\text{in}}$ and $\psi_{n,\text{out}}$ are spatially localized far from the origin with momenta that point roughly toward or away from the origin respectively. These phase space properties of $\psi_{n,\text{in/out}}$
guarantee that
\[
\lim_{n \to \infty} \| (\Omega^- - \text{id}) \psi_{n,\text{out}} \| = 0
\]
\[
\lim_{n \to \infty} \| (\Omega^+ - \text{id}) \psi_{n,\text{in}} \| = 0
\]
from which asymptotic completeness is an easy consequence.

In trying to apply the above outline to our setting verbatim, one encounters the problem that one cannot use the RAGE theorem to see that a continuous state moves away from the surface, as the surface is not compact. To proceed, we provide a novel interpretation of Enss original argument that does not rely on any a priori properties of the continuous subspace. Working in the original Enss setting, we fix a state \( \psi \) orthogonal to \( \text{Ran}(\Omega^-) \) and perform a phase space decomposition along an arbitrary time sequence increasing to infinity, now keeping the piece of \( \psi \) close to the origin (in the above, this piece was \( o(1) \) by the RAGE theorem):
\[
\psi_n = \psi_{n,\text{bounded}} + \psi_{n,\text{in}} + \psi_{n,\text{out}} + o(1)
\]
Here, \( \psi_n = e^{-it_n H} \psi \) as before and \( \psi_{n,\text{bounded}} \) is essentially \( \chi_{B_n} \psi_n \). One can argue that \( \psi_{n,\text{in}} \) goes to 0 as \( n \to \infty \) and the fact that \( \psi \perp \text{Ran}(\Omega^-) \) implies the same for \( \psi_{n,\text{out}} \). Thus, \( \psi_n \) is asymptotically equal to \( \psi_{n,\text{bounded}} \) and by varying over all time sequences one may show that
\[
\lim_{n \to \infty} \lim_{t \to \infty} \| \chi_{B_n} \psi_t \| = \| \psi \|
\]
In other words, Enss’ argument provides a geometrical characterization of the orthogonal complement of \( \text{Ran}(\Omega^-) \) as the set of bound states. Indeed, it is a consequence of the RAGE theorem that the states satisfying (1.3.1) are precisely the pure point states of \( H \), but one need not know this to obtain this interesting theorem.

Our adaptation of this argument to surface scattering will require that the operators implementing the phase space decomposition have better monotonicity properties than those originally used by Enss. To this end, we adopt Davies’ \([6]\) point of view on the Enss’ method by defining families of phase space observables. This formulation allows us to define the decomposition in a natural way, via operators which are almost projections onto subsets of phase space. For the reader’s convenience, we have collected various results about these observables in Appendix A. This is particularly important because throughout the proof we will use a phase space characterization of the surface states. The precise definition of this characterization will be given in Section 2.2, but for now it can be described as consisting of states that either evolve close to the surface or propagate away from the surface with momenta roughly parallel to the surface.

**Remark.** A natural question that arises from these two characterisations of \( \mathcal{H}_{\text{sur}} \) is: can there truly be surface states that propagate away from the subspace? If so, these states would have to do so at a sublinear rate and with highly restricted momenta. Indeed, following \([7]\), one may define
\[
\mathcal{H}_{\text{sur}}'(H) = \{ \psi \mid \lim_{R \to \infty} \sup_{t \geq 0} \| \chi_{S_R^{\epsilon}} e^{-itH} \psi \| = 0 \}
\]
which contains all states that evolve close to the subspace. This definition will be convenient to work with in Section 6. As shown in Proposition 6.1, \( \mathcal{H}_{\text{sur}}' \subset \mathcal{H}_{\text{sur}} \), so we may reformulate our question as: is there some choice of potential \( V \) so that \( \mathcal{H}_{\text{sur}} \setminus \mathcal{H}_{\text{sur}}'(H) \) is non-empty?
We will show in Section \( \text{6} \) that at least for \( V \) partially periodic or \( V \) that decays to a limit at \( \infty \) quickly enough, \( \mathcal{H}_\text{sur}' = \mathcal{H}_\text{sur} \). In both of these cases, one can also show the absence of singular continuous spectrum. We conjecture that there exists \( V \) such that there are singular continuous states inside \( \mathcal{H}_\text{sur} \setminus \mathcal{H}_\text{sur}'(H) \). Thus, one way to build such states might be to first construct \( V \) as above so that \( \mathcal{H} \) has singular continuous spectrum.

**Outline of paper.** In Section \( \text{2} \) we provide some notation as well as define \( \tilde{\mathcal{H}}_{\text{sur}} \), the auxiliary surface subspace that will be used in the proof of Theorem \( \text{1.1} \) extensively. In Section \( \text{3} \) we prove \( \text{(i)} \) of Theorem \( \text{1.1} \) in other words the existence of scattering states. In Section \( \text{4} \) we develop the Enns decomposition (Theorem \( \text{4.1} \)) for our setting, stated using the phase space observables of Davies. The decomposition is proved, as in the original Enss paper \( \text{[11]} \), by combining Cook’s method with several applications of non-stationary phase. This decomposition is the main ingredient used to show, in Section \( \text{5.1} \) that \( \mathcal{H}_\text{sur} \) and \( \text{Ran}(\Omega^\pm) \) span all of \( \mathcal{H} \), as described in the sketch above. In Section \( \text{5.2} \) we show that the intersection of these two subspaces is trivial, yielding our first completeness result (Lemma \( \text{5.2} \)). For this, we show that the intersection is unitarily equivalent to \( \tilde{\mathcal{H}}_{\text{sur}}(H_0) \), the surface states of the free evolution, which we show to be trivial by a direct computation. Then, we again use the method of non-stationary phase to give a better characterization of the surface states, namely to show that \( \tilde{\mathcal{H}}_{\text{sur}} \) is in fact equal to \( \mathcal{H}_\text{sur} \). In Section \( \text{6} \) we consider some special classes of potentials and discuss their surface states, relating them to known results where
relevant. Finally, in Appendix B we explain how to accommodate short range decay of the potential away from the surface.

**Acknowledgment.** We are grateful to our advisor, Wilhelm Schlag, for leading us towards this problem, and for his guidance and encouragement during this work.
2. Definitions and Results

2.1. Notation and Conventions.

- We let $\mathcal{H}$ denote $L^2(\mathbb{R}^d)$ with norm $\| \cdot \|$ and use the convention that its inner product $\langle \cdot, \cdot \rangle$ is anti-linear in the first argument and linear in the second.
- The symbols $\| \cdot \|$ and $\langle \cdot, \cdot \rangle$ will also be used for the norm and inner product on $\mathbb{R}^d$.
- $d(\cdot, \cdot)$ is used for the distance between points or subsets of $\mathbb{R}^d$.
- $B_r$ will mean the ball of radius $r$ centered at the origin in either $\mathbb{R}^d$ or $\mathcal{H}$ depending on context.
- For $A \subset \mathbb{R}^d$, $A^c$ denotes its complement.
- $\chi_A$ will mean the indicator function of $A \subset \mathbb{R}^d$.
- $A \Subset B$ denotes that $A$ is compactly contained in $B$.
- $\mathcal{S} = \mathcal{S}(\mathbb{R}^d)$, the Schwartz space.
- We use the following convention for the Fourier transform of $f \in \mathcal{H}$:
  $$\hat{f}(\xi) = \mathcal{F}(f)(\xi) = (2\pi)^{-\frac{d}{2}} \int_{\mathbb{R}^d} f(x)e^{-ix\xi} \, dx$$
  $$\mathcal{F}^{-1}(\hat{f})(x) = (2\pi)^{-\frac{d}{2}} \int_{\mathbb{R}^d} \hat{f}(\xi)e^{ix\xi} \, d\xi$$
- For $x = (x_1, \ldots, x_d) \in \mathbb{R}^d = \mathbb{R}^k \times \mathbb{R}^{d-k}$ we will often write $x^\parallel = (x_1, \ldots, x_k)$ and $x^\perp = (x_{k+1}, \ldots, x_d) \in \mathbb{R}^{d-k}$ for $k$ some integer $1 \leq k \leq d - 1$.
- $S_R \subset \mathbb{R}^d$ is the set of points within $R$ of $\mathbb{R}^k \times \{0\}$:
  $$S_R = \{ x \in \mathbb{R}^d \mid \|x^\perp\| \leq R \}$$
- We define the following family of subsets of $\mathbb{R}^d$
  $$A_{n,m} = \{ x \mid m\|x^\perp\| > \|x^\parallel\| + mn \}$$
  for $n > 0$ and $m := \cot(\gamma)$ for $\gamma \in (0, \frac{\pi}{2})$.
- For $\beta \in (0, \frac{\pi}{2})$, define $\mathcal{C}_\beta = A_{0,\cot(\beta)}$, for $\beta \in (0, \frac{\pi}{2})$.
- For $\alpha > 0$ and $\beta \in (0, \frac{\pi}{2})$, define the following family of subspaces of $\mathcal{H}$
  $$\mathcal{D}_{\alpha,\beta} = \{ \psi \in \mathcal{S} \mid \text{supp } \hat{\psi} \subset \mathcal{C}_\beta \cap B_\alpha \}$$
- For the definitions of $P_\delta(E)$ and $\hat{\eta}_{x,p,\delta}$ see Section 2.2 below.

2.2. Definition of the auxiliary surface subspace. As mentioned above, for the proof of part (ii) of Theorem 1.1 it will be more convenient to work with a different subspace, denoted $\mathcal{H}_{\text{surf}}$. We will show in Section 5.3 that it is in fact equal to $\mathcal{H}_{\text{surf}}$. The definition of this subspace and the arguments that follow depend crucially on the ability to localize a state into a subset of phase space. For this, we will follow the formulation of phase space observables developed in [2]. To this end, choose $\eta \in \mathcal{S}$, such that $\|\eta\| = 1$ and $\text{supp } \hat{\eta} \subset B_1$.

Let $\eta_\delta$ be such that $\hat{\eta}_\delta(p) = \delta^{-\frac{d}{2}} \hat{\eta}(\frac{p}{\delta})$, a rescaling of $\eta$, so that $\text{supp } \hat{\eta}_\delta \subset B_\delta$ and $\|\eta_\delta\| = 1$.

Now define the following family of coherent states by translating $\eta_\delta$ in phase space:
$$\hat{\eta}_{x,p,\delta}(\xi) = e^{-i\xi x} \eta_\delta(\xi - p)$$
or equivalently
$$\eta_{x,p,\delta}(y) = e^{ip(y-x)} \eta_\delta(y - x)$$
We use this to define a family, depending on \( \delta > 0 \), of positive-operator-valued measures as in [6], which serve as phase space observables. For any \( E \subset \mathbb{R}^{2d} \) Borel and \( \psi \in \mathcal{H} \) let

\[
P_\delta(E)\psi = (2\pi)^{-d} \int_E \langle \eta_{x,p;\delta}, \psi \rangle \eta_{x,p;\delta} \, dx \, dp
\]

which is a weakly convergent integral. These operators are closely related to the Fourier-Bargmann transform \( \mathcal{F}_{\eta_\delta} : L^2(\mathbb{R}^d) \to L^2(\mathbb{R}^{2d}) \) defined, for instance, in [1] Section 1.3.3. In our notation, \( \mathcal{F}_{\eta_\delta} \) may be written as

\[
(\mathcal{F}_{\eta_\delta}\psi)(x,p) = (2\pi)^{-\frac{d}{2}} \langle \eta_{x,p;\delta}, \psi \rangle
\]

Using this, we can write \( P_\delta(E) \) as

\[
P_\delta(E)\psi = (2\pi)^{-\frac{d}{2}} \int_E (\mathcal{F}_{\eta_\delta}\psi)(x,p) \eta_{x,p;\delta} \, dx \, dp = \mathcal{F}_{\eta_\delta}^* \chi_E \mathcal{F}_{\eta_\delta} \psi
\]

where \( \mathcal{F}_{\eta_\delta}^* \) is the adjoint of \( \mathcal{F}_{\eta_\delta} \). Note that \( P_\delta(E) \) is self-adjoint and non-negative by construction. See [4] for more details about the basic properties of these positive-operator-valued measures.

Recall that \( C_\beta = A_{0,\cot(\beta)}^c \) so that when \( k = 1 \), \( C_\beta \) is simply the union of the cone with vertex at the origin of aperture \( 2\beta \) in the \( e_1 \) direction and the cone with vertex at the origin of aperture \( 2\beta \) in the \(-e_1 \) direction.

For \( n > 0 \), \( m > 1 \), and angle \( \theta \in (0, \frac{\pi}{2}) \), we define the far set in phase space, which has space coordinates in \( A_{n,m} \) and momentum coordinates which make angle greater than \( \theta \) with the subspace, as well as its complement, the surface set:

\[
W_{n,\text{far}}^{m,\theta} = \{(x,p) \in \mathbb{R}^{2d} \mid (x,p) \in A_{n,m} \times C_\theta^c\}
\]

\[
W_{n,\text{sur}}^{m,\theta} = (W_{n,\text{far}}^{m,\theta})^c = \{(x,p) \in \mathbb{R}^{2d} \mid (x,p) \in A_{n,m}^c \times \mathbb{R}^d \cup A_{n,m} \times C_\theta\}
\]

Let \( \mathcal{N}_H^{m,\theta} : \mathcal{H} \to \mathbb{R}^+ \) denote the family of continuous seminorms

\[
\mathcal{N}_H^{m,\theta}(\psi) = \limsup_{\delta \to 0} \limsup_{n \to \infty} \sup_{t \geq 0} \| P_\delta(W_{n,\text{far}}^{m,\theta}) e^{-itH} \psi \|
\]

This allows us to define the set of surface states as

\[
\mathcal{H}_{\text{sur}}(H) = \bigcap_{m>1} \bigcap_{\theta \in (0,\frac{\pi}{2})} \{ \psi \in \mathcal{H} \mid \mathcal{N}_H^{m,\theta}(\psi) = 0 \}
\]

which shows that this is a closed subspace. The expression \( \mathcal{H}_{\text{sur}} \) without an operator will be used throughout to denote \( \mathcal{H}_{\text{sur}}(H) \).

3. Existence of the Wave Operators

To begin, we use the following direct application of the Corollary to Theorem XI.14 from [21]:

**Lemma 3.1.** Let \( u \) be a Schwartz function such that \( \overset{\circ}{u} \) has compact support. Let \( G \) be an open set containing the compact set \( \{ 2\xi \mid \xi \in \text{supp} \overset{\circ}{u} \} \). Then for any \( \ell \in \mathbb{N}, \) there is a constant \( C > 0 \) depending on \( \ell, u, \) and \( G \) so that

\[
|e^{-itH_0}u(x)| \leq C(1 + \|x\| + |t|)^{-\ell}
\]

for all pairs \((x,t)\) such that \( \frac{x}{t} \notin G \).
This is already enough to prove the existence of the wave operators:

Proof of part (i) of Theorem 1.1. By Cook’s method (see [21] Theorem XI.4), it suffices to show that for $D$ a dense set in $H$

$$\forall \psi \in D, \int_0^\infty \|V e^{-itH_0} \psi\| dt < \infty$$

To this end, for $\alpha > 0$ and $\beta \in (0, \frac{\pi}{2})$, define

$$D_{\alpha,\beta} = \{ \psi \in S | \text{supp } \hat{\psi} \subset C^c_\beta \cap B^c_\alpha \}$$

For fixed $\psi \in D_{\alpha,\beta}$

$$\|V e^{-itH_0} \psi\|^2 = \int_{\mathbb{R}^d} |V(x)(e^{-itH_0} \psi)(x)|^2 dx \leq M \int_{S_{r_0}} |e^{-itH_0} \psi(x)|^2 dx \quad \text{(3.0.1)}$$

It is easy to check that for fixed $0 < \beta < \frac{\pi}{2}$ and $\alpha > 0$, there is some $R > 0$ such that $S_{r_0} \subset C_\beta \cup B_R$. Furthermore,

$$\{2\xi | \xi \in \text{supp } \hat{\psi}\} \subset C^c_\beta \cap B^c_{2\alpha}$$

where we have used the scaling invariance of $C_\beta$. Thus, if $t > \frac{R}{2\alpha}$ and $x \in S_{r_0}$, $\frac{x}{t} \not\in C^c_\beta \cap B^c_{2\alpha}$ because

$$\frac{x}{t} \not\in C^c_\beta \cap B^c_{2\alpha} \iff x \in C_\beta \cup B_{2\alpha} \iff x \in C_\beta \cup B_{2\alpha t}$$

again due to the scaling invariance of $C_\beta$. Therefore, we may apply Lemma 3.1 to see that for any $\ell > 0$

$$|e^{-itH_0} \psi(\xi)| \leq C(1 + \|x\| + |t|)^{-\ell}$$

for all $x \in S_{r_0}$ and $t > \frac{R}{2\alpha}$ where $C$ is independent of $x$ and $t$. Choosing $\ell$ large enough, we get that for all $t > \frac{R}{2\alpha}$

$$\|V e^{-itH_0} \psi\|^2 \leq C \int_{S_{r_0}} |e^{-itH_0} \psi(x)|^2 dx \leq C \int_{S_{r_0}} (1 + \|x\| + t)^{-\ell} dx \leq C(1 + t)^{-\ell + d} \quad \text{(3.0.2)}$$

where $C$ denotes a constant which may change from line to line but is always independent of $x$ and $t$. It follows immediately that

$$\int_0^\infty \|V e^{-itH_0} \psi\| dt < \infty$$

so that by Cook’s method $\Omega^- \psi$ exists. Since $\bigcup_{\alpha > 0} \bigcup_{\frac{\pi}{2} > \beta > 0} D_{\alpha,\beta}$ is dense in $H$, we conclude that $\Omega^- \psi$ exists for all $\psi \in H$ and the claim for $\Omega^+$ follows from a similar argument.

The inclusion $\sigma(H_0) \subset \sigma_{ac}(H)$ is a result of the intertwining property of $\Omega^\pm$: $\Omega^\pm$ defines a unitary equivalence between $H_0$ and $H|_{\Omega^\pm(H)}$ and $\sigma(H_0)$ is purely absolutely continuous. □
4. ENS Decomposition

We fix $m > 1$ and $\theta \in (0, \frac{\pi}{2})$ in order to prove the following decomposition lemma. Since $m$ and $\theta$ are fixed in this lemma and its proof, we will often suppress them in the notation. However, it should be noted that the decomposition does depend on $m$ and $\theta$.

**Theorem 4.1.** Let $\{\varphi_n\}_{n=0}^{\infty} \subset \mathcal{H}$ be a sequence of unit vectors such that for some $0 < a < b$

$$\chi_{(-a^2,a^2)}(H)\varphi_n = \chi_{(a^2,\infty)}(H)\varphi_n = 0$$

for all $n$. Then for any $m > 1$, $\theta \in (0, \frac{\pi}{2})$, there exists some $\delta_0 = \delta_0(a,\theta)$, so that for all $\delta \in (0, \delta_0)$ we may write

$$\varphi_n = \varphi_{n;\text{out}} + \varphi_{n;\text{in}} + \varphi_{n;\text{sur}} + \varphi_{n;\text{w}}$$

where these summands satisfy

$$\lim_{n \to \infty} \| (\Omega - \text{id})\varphi_{n;\text{out}}\| = \lim_{n \to \infty} \| (\Omega^+ - \text{id})\varphi_{n;\text{in}}\| = 0 \quad (a)$$

$$\lim_{n \to \infty} \| \varphi_{n;\text{w}}\| = 0 \quad (b)$$

$$\varphi_{n;\text{sur}} = P_\delta(W_{n;\text{sur}}^m)\varphi_n \quad (c)$$

If additionally $\varphi_n = e^{-it\mathcal{H}}\varphi$ for some sequence of positive times $\{t_n\}_{n=0}^{\infty}$ then

$$\lim_{n \to \infty} \| \varphi_{n;\text{in}}\| = 0 \quad (d)$$

**Proof of Theorem 4.1.** Define the following subsets of $\mathbb{R}^{2d}$

$$W_{n;\text{out}}^{m,\theta,\delta} = \{(x, p) \in W_{n;\text{far}}^m \mid \langle x^+, p^+ \rangle \geq 0 \land \frac{a}{2} - \delta < \| p \| < 2b + \delta\}$$

$$W_{n;\text{in}}^{m,\theta,\delta} = \{(x, p) \in W_{n;\text{far}}^m \mid \langle x^+, p^+ \rangle < 0 \land \frac{a}{2} - \delta < \| p \| < 2b + \delta\}$$

$$W_{n;\text{w}}^{m,\theta,\delta} = \{(x, p) \in W_{n;\text{far}}^m \mid \| p \| \geq 2b + \delta \lor \| p \| \leq \frac{a}{2} - \delta\}$$

and let

$$\varphi_{n;\text{out}} = P_\delta(W_{n;\text{out}}^{m,\theta,\delta})\varphi_n \quad \varphi_{n;\text{in}} = P_\delta(W_{n;\text{in}}^{m,\theta,\delta})\varphi_n \quad \varphi_{n;\text{sur}} = P_\delta(W_{n;\text{sur}}^m)\varphi_n \quad \varphi_{n;\text{w}} = P_\delta(W_{n;\text{w}}^{m,\theta,\delta})\varphi_n$$

so that (c) holds. We naturally have

$$P_\delta(W_{n;\text{far}}^m)\varphi_n = \varphi_{n;\text{out}} + \varphi_{n;\text{in}} + \varphi_{n;\text{w}}$$

since $W_{n;\text{far}}^m = W_{n;\text{out}}^{m,\theta,\delta} \sqcup W_{n;\text{in}}^{m,\theta,\delta} \sqcup W_{n;\text{w}}^{m,\theta,\delta}$.

As mentioned, we will suppress the dependence on $m$ and $\theta$. We will also suppress the dependence of $W_{n;\text{in/out/w}}$ on $\delta$, indicating where relevant its dependence on $\theta$ and $a$.

Choose $\Phi$ continuous such that $\Phi(x) = 0$ for $x > 4b^2$ and $|x| < \frac{a^2}{4}$ and $\Phi = 1$ on $[\inf \sigma(H), -a^2] \cup [a^2, b^2]$. The rest of the proof will be contained in the following lemmas.

**Lemma 4.2.** Let $\Phi$ be a continuous function on $\mathbb{R}$ vanishing at $\infty$. If $B \subset \mathbb{R}^d$ is any Borel set and $E_n = A_{n,m} \times B$ then

$$\lim_{n \to \infty} \| P_\delta(E_n)(\Phi(H) - \Phi(H_0))\|_{op} = 0$$

for any $\delta > 0$ and fixed $m > 1$. 
Proof of Lemma 4.2. As in the proof of Lemma 1 to Theorem XI.113 in [21], since \((H-z)^{-1} - (H_0-z)^{-1}\) is bounded and analytic uniformly in \(\text{Re} z < \inf(\sigma(H))\), by the Vitali convergence theorem and Stone-Weierstrass, it is enough to prove the claim for \(\Phi(x) = (x-z)^{-1}\), where \(z < \inf(\sigma(H))\). By the resolvent identity, we may write
\[
\|P_\delta(E_n)(\Phi(H) - \Phi(H_0))\|_\text{op}^2 = \|P_\delta(E_n)(H_0 - z)^{-1}(-V)(H - z)^{-1}\|_\text{op}^2
\leq \|P_\delta(E_n)(H_0 - z)^{-1}V\|_\text{op}^2 \inf((H - z)^{-1})^2
\]
Note that the second term is finite as it is bounded by \(d(z, \sigma(H))^{-2}\).

Now we turn to estimating the first term. By Proposition A.7 since \(d(A_{n,m}, A_{n,m})\) is proportional to \(n\), we can write for any \(\varphi \in \mathcal{H}\)
\[
\lim_{n \to \infty} \|P_\delta(E_n)(H_0 - z)^{-1}V\|_\text{op}^2 \leq \|(H_0 - z)^{-1}V\|_\text{op}^2 \lim_{n \to \infty} \|\chi_{A_{n,m}}(H_0 - z)^{-1}V\|_\text{op}^2
\]
Since \(\|(H_0 - z)^{-1}V\|_\text{op}^2\) is bounded (as \(z < \inf(\sigma(H))\)) and \(\|V\|_\text{op} = M\), it is enough to show that \(\|\chi_{A_{n,m}}(H_0 - z)^{-1}V\|_\text{op}^2 \to 0\).

To this end, we first write
\[
\|\chi_{A_{n,m}}(H_0 - z)^{-1}V\|_\text{op}^2 = \int_{A_{n,m}} \left| \int_{S_{z_0}} G_z(y - x)V(y)\psi(y) \, dy \right|^2 \, dx
\]
where \(G_z(\cdot)\) is the Green’s function of \(H_0\) at \(z\). We recall that for \(\|x - y\| \geq 1\), \(\|G_z(x - y)\| \leq Ce^{-\frac{\beta}{2}\|x - y\|}\) for some constants \(\beta\) and \(C\) depending on \(z\). Thus, we may bound, for \(n > r_0 + 1\)
\[
\|\chi_{n,m}(H_0 - z)^{-1}V\|_\text{op}^2 \leq C\|V\|_\text{op}^2 \int_{A_{n,m}} \int_{S_{z_0}} e^{-\beta\|x - y\|} \, dy \, dx
\]
so to conclude we need only show that the above integral goes to 0 with \(n\). For this, we first consider the inner integral
\[
\int_{S_{z_0}} e^{-\beta\|x - y\|} \, dy \leq C \int_{\mathbb{R}^k} e^{-\beta\sqrt{\|x - y\|^2 + (\|x\| - r_0)^2}} \, dy \leq C \int_{\mathbb{R}^k} e^{-\frac{\beta}{\sqrt{2}}(\|y\| + \|x\| - r_0)} \, dy
\leq C e^{-\frac{\beta}{\sqrt{2}}\|x\|}
\]
where \(C\) depends only on \(r_0\) and \(z\). Turning to the outer integral, for \(C\) depending only on \(r_0, z,\) and \(m\) we write
\[
\int_{A_{n,m}} \int_{S_{z_0}} e^{-\frac{\beta}{\sqrt{2}}\|x - y\|} \, dy \, dx \leq C \int_{A_{n,m}} \int_{\mathbb{R}^{d-k}\{x^k \in \mathbb{R}^k : \|x^k\| < m \|x\| - mn\}} e^{-\frac{\beta}{\sqrt{2}}\|x\|} \, dx \, dx^k
\leq C \int_{\|x^k\| \geq n} (\|x\| - n)^k e^{-\frac{\beta}{\sqrt{2}}\|x\|} \, dx^k \xrightarrow{n \to \infty} 0
\]
where the limit comes from the fact that the integral is clearly convergent and the integrand goes to 0 monotonically with \(n\).

This lemma is enough to show (b):

**Corollary 4.3.**
\[
\|\varphi_{n,w}\| \xrightarrow{n \to \infty} 0
\]
Proof of Corollary. Note that for any state $\psi$, $\Phi(H_0)\psi$ has Fourier support contained in $\{\xi | \frac{\pi}{2} < \|\xi\| < 2b\}$. In particular, by Proposition A.6 this means that
\[ P_\delta(W_{n,w})\Phi(H_0)\varphi_n = 0 \]
\[ \varphi_{n,w} = P_\delta(W_{n,w})\varphi_n = P_\delta(W_{n,w})(1 - \Phi(H_0))\varphi_n \]
so we can write
\[ \|\varphi_{n,w}\| = \|P_\delta(W_{n,w})(1 - \Phi(H_0))\varphi_n\| \]
\[ \leq \|P_\delta(W_{n,w})(1 - \Phi(H))\varphi_n\| + \|P_\delta(W_{n,w})(\Phi(H) - \Phi(H_0))\varphi_n\| \]
The first summand is 0 by the assumption on $\varphi_n$. By the lemma above, the second summand goes to zero (since $W_{n,w} = A_{n,m} \times E$ for some $E$). So we conclude:
\[ \|\varphi_{n,w}\| \xrightarrow{n \to \infty} 0 \]
as needed. □

Lemma 4.4.
\[ \|(\Omega^- - \text{id})\varphi_{n,\text{out}}\| \xrightarrow{n \to \infty} 0 \quad (4.0.2) \]
\[ \|(\Omega^+ - \text{id})\varphi_{n,\text{in}}\| \xrightarrow{n \to \infty} 0 \quad (4.0.3) \]

Proof. We may write
\[ \|(\Omega^- - \text{id})\varphi_{n,\text{out}}\| \leq \int_0^\infty e^{i\mathcal{H}(H - H_0)}e^{-i\mathcal{H}_0} dt \varphi_{n,\text{out}} \leq \int_0^\infty \|Ve^{-i\mathcal{H}_0}\varphi_{n,\text{out}}\| dt \]
\[ \leq M \int_0^\infty \|\chi_{S_{\eta_0}}e^{-i\mathcal{H}_0}\varphi_{n,\text{out}}\| dt \quad (4.0.4) \]
since $V$ is supported on $S_{\eta_0}$ and $M = \|V\|_{\text{op}}$.

To proceed, we want to show that for any $\ell > 0$
\[ \|\chi_{S_{\eta_0}}e^{-i\mathcal{H}_0}P_\delta(W_{n,\text{out}})\|_{\text{op}} \leq C(n + t)^{-\ell} \quad (4.0.5) \]
for $C = C(\delta, a, \ell, d, m)$ independent of $n$ and $t$, from which (4.0.2) follows in light of (4.0.4).

In what follows, the symbol $C$ refers to such a constant, the exact value of which may change from line to line.

From Proposition A.5 we have that
\[ \|\chi_{S_{\eta_0}}e^{-i\mathcal{H}_0}P_\delta(W_{n,\text{out}})\|_{\text{op}}^2 \leq (2\pi)^{-d} \int_{W_{n,\text{out}}} \|\chi_{S_{\eta_0}}e^{-i\mathcal{H}_0}\eta_{x,p,\delta}\|^2 dx dp \quad (4.0.6) \]
which we will estimate via the following lemma:

Lemma 4.5 (Lemma 2 of Theorem XI.112 in [21]). Let $K$ be a compact subset of $\mathbb{R}^d$ and let $\mathcal{O}$ be an open neighborhood of $K$. Let $C(x_0, t) = \{x_0 + vt \mid v \in \mathcal{O}\}$ be the classically allowed region for particles starting at $x_0$ with velocities in $\mathcal{O}$. Then, for any $\ell$ there is a number $\mu$ and a constant $D = D(K, \mathcal{O}, \ell, d)$ so that:
\[ |e^{-i\mathcal{H}_0}u(x)| \leq D(1 + d(x, C(x_0, t)))^{-\ell}\|(1 + | \cdot - x_0|^\mu)u\| \]
for all $u$ with supp $\hat{u} \subset K$ and all $x \notin C(x_0, t)$.
Claim 4.6. For $\delta(\theta, a) > 0$ small enough, there exist constants $0 < c < 1$ and $0 < c' < \frac{1}{2}$ such that

$$
\|\xi^\perp\| > c
$$

$$
\langle x^\perp, \xi^\perp \rangle \geq -c'\|x^\perp\|\|\xi^\perp\|
$$

for all $\xi \in O := \text{supp} \hat{\eta}_{x,p,\delta} + B_\delta$, an open neighborhood, where $(x, p) \in W_{n,\text{out}}$.

**proof of claim.** We may write $\xi = p + p'$ with $\|p'\| < 2\delta$. It is easy to see that the condition $p \in \mathcal{C}_\delta$ is equivalent to $\|p^\perp\| \geq \sin(\theta)\|p\|$, so we can write

$$
\|p^\perp\| \geq \sin(\theta)\|p\| \geq \sin(\theta)(\frac{a}{2} - \delta) \implies
$$

$$
\|\xi^\perp\| \geq \sin(\theta)(\frac{a}{2} - \delta) - 2\delta
$$

which is positive for $\delta$ in a neighborhood of 0 (with width depending on $\theta$ and $a$). Therefore, the existence of $c$ is assured.

To see the existence of $c'$, using $\langle x^\perp, p^\perp \rangle \geq 0$ we get that

$$
\frac{\langle x^\perp, \xi^\perp \rangle}{\|x^\perp\|\|\xi^\perp\|} \geq \frac{\langle x^\perp, (p')^\perp \rangle}{\|x^\perp\|\|\xi^\perp\|} \geq -\frac{2\delta}{\sin(\theta)(\frac{a}{2} - \delta) - 2\delta}
$$

where the latter quantity is greater than $-\frac{1}{2}$ as long as $\delta > 0$ is within a neighborhood of 0, again depending on $\theta$ and $a$. \qed

Claim 4.7. Let $C = \frac{1}{8}\min(1, c)$. Then if $n \geq 8r_0$

$$
\|x^\perp + t\xi^\perp - y^\perp\| \geq C(\|x^\perp\| + n + t)
$$

for all $(x, p) \in W_{n,\text{out}}$, $t \geq 0$, $y \in S_{r_0}$, and $\xi \in O$.

**proof of claim.** We consider $\xi \in O$. Using the claim above, we have that

$$
\|x^\perp + t\xi^\perp\|^2 = \|x^\perp\|^2 + t^2\|\xi^\perp\|^2 + 2t\langle x^\perp, \xi^\perp \rangle \geq \|x^\perp\|^2 + t^2\|\xi^\perp\|^2 - 2tc'\|x^\perp\|\|\xi^\perp\|
$$

$$
= \frac{1 - c'}{2}(\|x^\perp\| + t\|\xi^\perp\|)^2 + \frac{1 + c'}{2}(\|x^\perp\| - t\|\xi^\perp\|)^2
$$

$$
\geq \frac{1 - c'}{2}(\|x^\perp\| + tc)^2 \geq \frac{1}{4}(\|x^\perp\| + tc)^2
$$

so that

$$
\|x^\perp + t\xi^\perp\| \geq \frac{1}{2}(\|x^\perp\| + ct)
$$

Furthermore, since $\|x^\perp\| > n$ (this follows immediately from the definition of $A_{n,m}$), we may write

$$
\|x^\perp + t\xi^\perp\| \geq \frac{1}{4}(\|x^\perp\| + n + ct)
$$

Finally, because $\|y^\perp\| \leq r_0 \leq \frac{1}{8}n$,

$$
\|x^\perp + t\xi^\perp - y^\perp\| \geq \frac{1}{4}(\|x^\perp\| + n + ct) - \|y^\perp\| \geq \frac{1}{8}(\|x^\perp\| + n + ct)
$$

By letting $C = \frac{1}{8}\min(1, c)$, we obtain the desired inequality for all $\xi \in O$. \qed
Let $C(x,t)$ be the classically allowed region (see Lemma 4.5) corresponding to $\mathcal{O}$. For $y$, $\xi$, and $(x,p)$ as above, this implies that
\[
\|x + t\xi - y\| \geq (\|x\| + t\|\xi\| - \|y\|)^2 + C(\|x\| + n + |t|)^{\frac{3}{2}} \tag{4.0.7}
\]
Furthermore, for all $\xi \in \mathcal{O}$
\[
\|x\| + t\|\xi\| - \|y\| \geq \max(\|x\| + tp - \|y\| - 2\delta t, 0)
\]
so that
\[
d(y,C(x,t)) \geq (\max(\|x\| + tp - \|y\| - 2\delta t, 0)^2 + C(\|x\| + n + t)^{\frac{3}{2}}
\]
In particular, $y \notin C(x,t)$ so we may apply Lemma 4.5 to see that for any $\ell > 0$ there is some $\mu > 0$ such that
\[
|\langle e^{-itH_0}\eta_{x,p,\delta}\rangle(y)| \leq D\frac{(1 + |\cdot - x|^\mu)\eta_{x,p,\delta}(\cdot)}{|d(y,C(x,t))|}\ell
\]
uniformly in $(x,p) \in W_{n,\text{out}}$ and $y \in S_{r_0}$. We note that
\[
\|(1 + |\cdot - x|^\mu)\eta_{x,p,\delta}(\cdot)\| \leq \|\eta_{x,p,\delta}\| + \left(\int_{\mathbb{R}^d}|y - x|^{2\mu}|\eta_\delta(y - x)|^2\,dy\right)^{\frac{1}{2}}
\]
where the latter expression is independent of $x$ and $p$ (but depends on $\delta$) and is finite since $\eta_\delta \in \mathcal{S}$. Therefore,
\[
\left\|\chi_{S_{r_0}} e^{-itH_0}\eta_{x,p,\delta}\right\|^2 \leq C\int_{\mathbb{R}^\ell} \int_{|y^\perp| \leq r_0} \left(\max(\|x\| + tp - \|y\| - 2\delta t, 0)^2 + (\|x\| + n + t)^{\frac{3}{2}}\right)^{-\ell} dy\,dy^\perp
\]
\[
\leq C\int_{\mathbb{R}^\ell} \left(\max(\|x\| + tp - \|y\| - 2\delta t, 0)^2 + (\|x\| + n + t)^{\frac{3}{2}}\right)^{-\ell} dy\|d^\perp
\]
\[
\leq C\left(\|x\| + n + t\right)^{-2\ell + 1}
\]
Using the above, for any $\ell$ large enough relative to $d$, we may write
\[
\int_{W_{n,\text{out}}} \int_{W_{n,\text{out}}} \|\chi_{S_{r_0}} e^{-itH_0}\eta_{x,p,\delta}\|^2 \,dx\,dp \leq C\int_{W_{n,\text{out}}} (\|x\| + n + t)^{-\ell} \,dx\,dp
\]
\[
\leq C\int_{B_{2\delta + A_{n,m}}} (\|x\| + n + t)^{-\ell} \,dx\,dp \leq C\int_{\mathbb{R}^{d-k}} \int_{\{x \in \mathbb{R}^k : |x| < m\|x\| - mn\}} (\|x\| + n + t)^{-\ell} \,dx\|d^\perp
\]
\[
\leq C\int_{\|x\| \geq n} m^k (\|x\| - n)^k (\|x\| + n + t)^{-\ell} \,dx\|d^\perp \leq C\int_n^\infty r^k (r + n + t)^{-\ell} r^{d-k-1} \,dr
\]
\[
\leq C(n + t)^{-\ell + d}
\]
where now $C$ depends additionally on $m$, but is still independent of $n$ and $t$. 

This establishes (4.0.6) which proves (4.0.2). The limit (4.0.3) may be deduced from exactly the same argument by first writing
\[
\|(\Omega^+ - \text{id})\varphi_{n;\text{in}}\| \leq M \int_{-\infty}^{0} \|\chi_{S_{r_0}} e^{-iH_0 t} \varphi_{n;\text{in}}\| \, dt
\]
and noting that for \( t \leq 0 \), \( e^{-itH_0} \varphi_{n;\text{in}} \) behaves like \( e^{-itH_0} \varphi_{n;\text{out}} \) for \( t \geq 0 \) because \( W_{n;\text{out}} \) and \( W_{n;\text{in}} \) are related by \( (x, p) \mapsto (x, -p) \).

\[ \square \]

**Lemma 4.8.** If we assume that \( \varphi_n = e^{-it_n H} \varphi \), for some sequence of positive times \( \{t_n\}_{n=0}^\infty \), then
\[
\|\varphi_{n;\text{in}}\| \xrightarrow{n \to \infty} 0
\]

**Proof.** This proof is based on an argument of Enss recorded in [26]. We can write
\[
\|\varphi_{n;\text{in}}\| = \|P_\delta(W_{n;\text{in}}) e^{-it_n H} \varphi\| \leq \|P_\delta(W_{n;\text{in}})(e^{-it_n H} - e^{-it_n H_0})\varphi\| + \|P_\delta(W_{n;\text{in}})e^{-it_n H_0} \varphi\|
\]
so it suffices to prove that
\[
\|P_\delta(W_{n;\text{in}})(e^{-it_n H} - e^{-it_n H_0})\|_{\text{op}} \xrightarrow{n \to \infty} 0 \quad (4.0.8)
\]
and
\[
\s-lim_{n \to \infty} P_\delta(W_{n;\text{in}}) e^{-it_n H_0} = 0 \quad (4.0.9)
\]

To prove (4.0.8), we write
\[
\|P_\delta(W_{n;\text{in}})(e^{-it_n H} - e^{-it_n H_0})\|_{\text{op}} = \|(e^{it_n H} - e^{it_n H_0}) P_\delta(W_{n;\text{in}})\|_{\text{op}}
\]
\[
= \|(\text{id} - e^{-it_n H} e^{it_n H_0}) P_\delta(W_{n;\text{in}})\|_{\text{op}} \leq \int_0^{t_n} \|Ve^{itH_0} P_\delta(W_{n;\text{in}})\|_{\text{op}} \, dt
\]
\[
\leq M \int_{0}^{t_n} \|\chi_{S_{r_0}} e^{irH_0} P_\delta(W_{n;\text{in}})\|_{\text{op}} \, d\tau \leq M \int_{0}^{\infty} \|\chi_{S_{r_0}} e^{irH_0} P_\delta(W_{n;\text{in}})\|_{\text{op}} \, d\tau
\]
The proof of (4.0.5) shows that for any \( \ell > 0 \)
\[
\|\chi_{S_{r_0}} e^{irH_0} P_\delta(W_{n;\text{in}})\|_{\text{op}} \leq C(n + \tau)^{-\ell}
\]
as long as \( \tau > 0 \), so we conclude that
\[
\int_{0}^{\infty} \|\chi_{S_{r_0}} e^{irH_0} P_\delta(W_{n;\text{in}})\|_{\text{op}} \, d\tau \xrightarrow{n \to \infty} 0
\]
thus establishing (4.0.8).

For (4.0.9), we fix \( \psi \in \mathcal{H} \) compactly supported and choose \( R \) so that \( \text{supp} \psi \subset S_R \). Then
\[
\|P_\delta(W_{n;\text{in}}) e^{-iH_0 t_0} \psi\| = \|P_\delta(W_{n;\text{in}}) e^{-iH_0 t_0} \chi_{S_R} \psi\| \leq \|\chi_{S_R} e^{iH_0 t_0} P_\delta(W_{n;\text{in}})\|_{\text{op}} \|\psi\| \xrightarrow{n \to \infty} 0
\]
because the computation of the above operator norm applies just as well to \( S_R \) for \( R > 0 \) arbitrary instead of \( S_{r_0} \). Density establishes (4.0.9), which concludes the proof of the lemma.

\[ \square \]

These lemmas establish Theorem 4.1 in full.
5. Proof of part (ii) of Theorem 1.1

The proof is accomplished in three steps: the first is to prove that \( \text{Ran} \Omega^- \) and \( \tilde{H}_{\text{sur}} \) span all of \( \mathcal{H} \), the second is to show that their intersection is 0, and the third is to prove that \( \tilde{H}_{\text{sur}} = H_{\text{sur}} \).

5.1. Step 1: The Span of \( \text{Ran} \Omega^- \) and \( \tilde{H}_{\text{sur}} \). The above decomposition theorem (Theorem 4.1), establishes the first step towards the proof of part (ii) of Theorem 1.1:

**Lemma 5.1.**

\[ \mathcal{H} = \tilde{H}_{\text{sur}} + \text{Ran}(\Omega^-) \]

**Proof.** Let \( \varphi \in (\text{Ran}(\Omega^-))^\perp \) be a state such that for some \( 0 < a < b < \infty \)

\[ \chi(-a^2,a^2)(H)\varphi = \chi(b^2,\infty)(H)\varphi = 0 \]

Now, fix \( m > 1, \theta \in (0, \frac{\pi}{2}) \) and for each \( n \) choose \( t_n \geq 0 \) such that

\[ \| P_\delta(W_{n;\text{far}}) e^{-it_n H} \varphi \| > \frac{1}{2} \sup_{t \geq 0} \| P_\delta(W_{n;\text{far}}) e^{-it H} \varphi \| \]  

(5.1.1)

Let \( \varphi_n = e^{-it_n H} \varphi \). By Theorem 4.1 there is a \( \delta_0(\theta, a) \) such that for all \( \delta < \delta_0 \), there is a decomposition depending on \( m, \theta \), and \( \delta \)

\[ \varphi_n = \varphi_{n;\text{out}} + \varphi_{n;\text{in}} + \varphi_{n;\text{sur}} + \varphi_{n;w} \]

obeying the properties in the theorem.

Now, since \( \varphi \perp \text{Ran}(\Omega^-) \), and the propagator leaves \( \text{Ran}(\Omega^-) \) invariant, we get that

\[ \lim_{n \to \infty} | \langle \varphi_n, \varphi_{n;\text{out}} \rangle | = \lim_{n \to \infty} | \langle \varphi_n, \Omega^- \varphi_{n;\text{out}} \rangle | = 0 \]

Furthermore \( \| \varphi_{\text{in}} \|_n \xrightarrow{n \to \infty} 0 \) and \( \| \varphi_{\text{w}} \|_n \xrightarrow{n \to \infty} 0 \) so that from property (c) in Theorem 4.1 and the fact that \( W_{n;\text{far}} \sqcup W_{n;\text{sur}} = \mathbb{R}^d \) we get that

\[ \langle P_\delta(W_{n;\text{far}}) \varphi_n, \varphi_n \rangle = \langle \varphi_{n;\text{in}} + \varphi_{n;\text{out}} + \varphi_{n;w}, \varphi_n \rangle \xrightarrow{n \to \infty} 0 \]

But this implies that

\[ \| P_\delta(W_{n;\text{far}}) \varphi_n \| \xrightarrow{n \to \infty} 0 \]

as

\[ \| P_\delta(W_{n;\text{far}}) \varphi_n \|^2 = \langle P_\delta^2(W_{n;\text{far}}) \varphi_n, \varphi_n \rangle \leq \langle P_\delta(W_{n;\text{far}}) \varphi_n, \varphi_n \rangle \]

where we have used that \( P_\delta^2(E) \leq P_\delta(E) \) as in the proof of Proposition A.7. Since the limit in \( n \) of the LHS in inequality (5.1.1) is 0 we conclude that the same is true of the RHS so that

\[ \lim_{n \to \infty} \sup_{t \geq 0} \| P_\delta(W_{n;\text{far}}) e^{-it H} \varphi \| = 0 \]

for all \( \delta < \delta_0(\theta, a) \). In other words, since the choice of \( m \) and \( \theta \) was arbitrary, we get that \( \varphi \in \tilde{H}_{\text{sur}} \).

The above proof only applies to \( \varphi \) with \( H \)-energy that is finite and bounded away from zero. But the set of such \( \varphi \) is dense in \( (\text{Ran}(\Omega^-))^\perp \) as it is dense in \( \mathcal{H} \), so that because \( \tilde{H}_{\text{sur}} \) is closed we see that

\[ (\text{Ran}(\Omega^-))^\perp \subset \tilde{H}_{\text{sur}} \]
which implies that $\mathcal{H} = \tilde{\mathcal{H}}_{\text{sur}} + \text{Ran}(\Omega^-)$  

5.2. Step 2: The Intersection of $\text{Ran} \Omega^-$ and $\tilde{\mathcal{H}}_{\text{sur}}$.

**Lemma 5.2.**

$$\mathcal{H} = \text{Ran}(\Omega^-) \oplus \tilde{\mathcal{H}}_{\text{sur}}$$

**Proof.** From Lemma 5.1, to prove this lemma all we have to do is show that $\text{Ran}(\Omega^-) \cap \tilde{\mathcal{H}}_{\text{sur}} = \{0\}$. For this, we will define the following auxiliary family of seminorms

$$\tilde{N}_{\mathcal{H}}^{m,\theta}(\psi) = \lim_{\delta \to 0} \lim_{n \to \infty} \lim_{t \to \infty} \left\| P_{\delta} \left( W_{m,\theta}^{n,\text{far}} \right) e^{-itH} \psi \right\|$$

by replacing $\sup_{t \geq 0}$ in the definition of $N_{\mathcal{H}}^{m,\theta}(\psi)$ with $\lim_{t \to \infty}$ so that we may define

$$\tilde{\mathcal{H}}_{\text{sur}}^{\lim,\sup}(H) := \bigcap_{m > 1} \bigcap_{\theta \in (0, \frac{\pi}{2})} \left\{ \psi \in \mathcal{H} \mid \tilde{N}_{\mathcal{H}}^{m,\theta}(\psi) = 0 \right\}$$

accordingly. Clearly, $\tilde{\mathcal{H}}_{\text{sur}} \subset \tilde{\mathcal{H}}_{\text{sur}}^{\lim,\sup}(H)$ and will prove the stronger claim that $\text{Ran}(\Omega^-) \cap \tilde{\mathcal{H}}_{\text{sur}}^{\lim,\sup}(H) = \{0\}$. To this end, we prove the following claim:

**Claim 5.3.** If $\psi \in \text{Ran}(\Omega^-) \cap \tilde{\mathcal{H}}_{\text{sur}}^{\lim,\sup}(H)$ then there exists $\varphi \in \tilde{\mathcal{H}}_{\text{sur}}^{\lim,\sup}(H_0)$ such that $\Omega^- \varphi = \psi$.

**Proof.** Let $\psi \in \text{Ran}(\Omega^-) \cap \tilde{\mathcal{H}}_{\text{sur}}^{\lim,\sup}(H)$. Since $\psi \in \text{Ran}(\Omega^-)$ there is some $\varphi \in \mathcal{H}$ such that:

$$\psi = \Omega^- \varphi$$

or equivalently

$$\lim_{t \to \infty} \left\| e^{-itH_0} \varphi - e^{-itH} \psi \right\| = 0$$

For any fixed $m > 1$, $\theta \in (0, \frac{\pi}{2})$, $\delta > 0$, $n > 0$, this implies that

$$\lim_{t \to \infty} \left\| P_{\delta} (W_{m,\theta}^{n,\text{far}}) e^{-itH} \psi - P_{\delta} (W_{m,\theta}^{n,\text{far}}) e^{-itH_0} \varphi \right\| \leq \lim_{t \to \infty} \left\| P_{\delta} (W_{m,\theta}^{n,\text{far}}) \right\|_{\text{op}} \left\| e^{-itH} \psi - e^{-itH_0} \varphi \right\|$$

$$= 0$$

so that

$$\lim_{t \to \infty} \left\| P_{\delta} (W_{m,\theta}^{n,\text{far}}) e^{-itH_0} \varphi \right\| \leq \lim_{t \to \infty} \left\| P_{\delta} (W_{m,\theta}^{n,\text{far}}) (e^{-itH_0} \varphi - e^{-itH} \psi) \right\| + \left\| P_{\delta} (W_{m,\theta}^{n,\text{far}}) e^{-itH} \psi \right\|$$

$$\leq \lim_{t \to \infty} \left\| P_{\delta} (W_{m,\theta}^{n,\text{far}}) e^{-itH} \psi \right\|$$

Therefore

$$\lim_{\delta \to 0} \lim_{n \to \infty} \lim_{t \to \infty} \left\| P_{\delta} (W_{m,\theta}^{n,\text{far}}) e^{-itH_0} \varphi \right\| \leq \lim_{\delta \to 0} \lim_{n \to \infty} \lim_{t \to \infty} \left\| P_{\delta} (W_{m,\theta}^{n,\text{far}}) e^{-itH} \psi \right\| = 0$$

since $\psi \in \tilde{\mathcal{H}}_{\text{sur}}^{\lim,\sup}(H)$ so that because $m$ and $\theta$ were arbitrary, we see that $\varphi \in \tilde{\mathcal{H}}_{\text{sur}}^{\lim,\sup}(H_0)$.

Thus, because $\Omega^-$ is an isometry, it suffices to show that $\tilde{\mathcal{H}}_{\text{sur}}^{\lim,\sup}(H_0) = \{0\}$:

**Claim 5.4.**

$$\tilde{\mathcal{H}}_{\text{sur}}^{\lim,\sup}(H_0) = \{0\}$$
Proof. Recall the following definition
\[ D_{\alpha, \beta} = \{ \varphi \in \mathcal{H} \mid \text{supp } \hat{\varphi} \subseteq C_{\beta}^c \cap B^c_{\alpha} \} \]
for some \( \alpha > 0, \beta \in (0, \frac{\pi}{2}) \).
We will show that \( \varphi \in D_{\alpha, \beta} \cap \mathcal{H}_{\text{lim sup}}(H_0) \) implies that \( \varphi = 0 \), from which the claim follows by the density of \( \bigcup_{\alpha > 0, \beta (0, \frac{\pi}{2})} D_{\alpha, \beta} \) in \( \mathcal{H} \).

Now, fix \( \varphi \in D_{\alpha, \beta} \cap \mathcal{H}_{\text{lim sup}}(H_0) \). For any \( \theta < \beta \), we claim that
\[ d(C^c_{\beta} \cap B^c_{\alpha}, C_\theta) > \alpha \sin(\beta - \theta) \]
To see this, first note that for \( x \in C^c_{\beta} \cap B^c_{\alpha} \) and \( y \in C_\theta \), \( \angle(x, y) > \beta - \theta \) as \( \angle(x, \text{Span}(\{e_j\}_{j=1}^k)) > \beta \) and \( \angle(y, \text{Span}(\{e_j\}_{j=1}^k)) < \theta \) and then write
\[ \|x - y\|^2 \geq \|y\|^2 - 2\|x\|\|y\| \cos(\beta - \theta) + \|x\|^2 = (\|y\| - \|x\| \cos(\beta - \theta))^2 + \|x\|^2 \sin^2(\beta - \theta) \]
from which the claim follows. Thus, for all \( \delta = \delta(\alpha, \beta, \theta) \) sufficiently small
\[ P_{\delta}(W_{n, \text{lim sup}}^m, \varphi) = P_{\delta}(A_{n, m}^c \times \mathbb{R}^d) \phi \]
as \( P_{\delta}(W_{n, \text{lim sup}}^m) = P_{\delta}(A_{n, m}^c \times \mathbb{R}^d) + P_{\delta}(A_{n, m} \times C_\theta) \) and \( P_{\delta}(A_{n, m} \times C_\theta) \psi = 0 \) by Proposition 5.6
Now, if \( m = m(\beta, \alpha) \) and \( n = n(\beta, \alpha) \) are sufficiently large, and \( t = t(n, m) \) is large enough, then \( \tilde{\tau} \notin C_{\beta}^c \cap B^c_{\alpha} \) for all \( x \in A_{n, m}^c \). Therefore, we may proceed as in the proof of (3.0.2) in the proof of part (i) of Theorem 1.1 to see that for all \( \ell > 0 \)
\[ \|\chi_{A_{n, m}^c} e^{-itH_0} \varphi\|^2 \leq C \int_{A_{n, m}^c} (1 + \|x\| + t)^{-\ell} \, dx \]
and therefore
\[ \lim_{t \to \infty} \|\chi_{A_{n, m}^c} e^{-itH_0} \varphi\| = 0 \]
for all \( n \) and \( m \) sufficiently large. By using Proposition 5.7 we can write:
\[ \lim_{n \to \infty} \lim_{t \to \infty} \|P_{\delta}(W_{n, \text{lim sup}}^m)e^{-itH_0} \varphi\|^2 \leq \|\varphi\| \lim_{n \to \infty} \lim_{t \to \infty} \|\chi_{A_{n, m}^c} e^{-itH_0} \varphi\|^2 = 0 \]

In summary, we have shown that we may find \( m_0 \) and \( \theta_0 \) such that for some \( \delta_0 \) if \( \delta < \delta_0 \) then
\[ \lim_{n \to \infty} \lim_{t \to \infty} \|P_{\delta}(W_{n, \text{lim sup}}^m)e^{-itH_0} \varphi\| = 0 \]
Now, because \( \varphi \in \mathcal{H}_{\text{lim sup}}(H_0) \), we may find \( \delta < \delta_0 \) so that
\[ \lim_{n \to \infty} \lim_{t \to \infty} \|P_{\delta}(W_{n, \text{far}}^m)e^{-itH_0} \varphi\| < \varepsilon \]
for any \( \varepsilon > 0 \). It follows that
\[ \|\varphi\| = \lim_{n \to \infty} \lim_{t \to \infty} \|P_{\delta}(W_{n, \text{lim sup}}^m)e^{-itH_0} \varphi + P_{\delta}(W_{n, \text{far}}^m)e^{-itH_0} \varphi\| < \varepsilon \]
and since \( \varepsilon \) was arbitrary, we see that \( \varphi = 0 \).

These claims complete the proof of Lemma 5.2.

It may be of interest to note that we have in fact proven that it is equivalent to define \( \mathcal{H}_{\text{sur}} \) with a lim sup in time instead of a sup. In other words:
Corollary 5.5. We have that
\[ H_{\text{sur}}^{\lim \sup} = \tilde{H}_{\text{sur}} \]

Proof. We have shown that
\[ \text{Ran}(\Omega^-) \cap H_{\text{sur}}^{\lim \sup} = \{0\} \]
and since \( H = \text{Ran}(\Omega^-) \oplus \tilde{H}_{\text{sur}} \) and \( \tilde{H}_{\text{sur}} \subset H_{\text{sur}}^{\lim \sup} \), we have in addition that:
\[ H = \text{Ran}(\Omega^-) + H_{\text{sur}}^{\lim \sup} \]
And the desired equality follows immediately. \( \square \)

5.3. Step 3: \( \tilde{H}_{\text{sur}} = H_{\text{sur}} \).

proof of part (ii) of Theorem 1.1. Recall the definition of surface states:
\[ H_{\text{sur}} = \{ \psi \in H \mid \forall m > 1, \forall v > 0, \lim_{t \to \infty} \| \chi_{A_{vt,m}} e^{-itH} \psi \| = \| \psi \| \} \]
Let us first establish that this is a closed set:

Proposition 5.6. \( H_{\text{sur}} \) is closed.

Proof. Suppose that \( \psi \in H_{\text{sur}} \) and \( \| \varphi - \psi \| < \epsilon \). Then for all \( v > 0 \) and \( m > 1 \) there is some sequence of times increasing to \( \infty \), \( \{t_n\}_{n=0}^\infty \) such that
\[ \| \chi_{A_{vt_n,m}} e^{-it_nH} \varphi \| < \epsilon \]
for all \( n \). Thus, the claim follows from that fact that
\[ \| \chi_{A_{vt_n,m}} e^{-it_nH} \varphi \| \leq \| \chi_{A_{vt_n,m}} e^{-it_nH} \psi \| + \| \chi_{A_{vt_n,m}} e^{-it_nH} (\varphi - \psi) \| < 2\epsilon \]
\( \square \)

Now, it will be convenient to define the subsets of phase space
\[ W_{n;\text{close}}^{m,\theta} = \{ (x,p) \in \mathbb{R}^{2d} \mid x \in A_{c,n,m} \} \]
\[ W_{n;\text{vert}}^{m,\theta} = \{ (x,p) \in \mathbb{R}^{2d} \mid x \in A_{n,m} \land p \in C_\theta \} \]
Naturally,
\[ W_{n;\text{close}}^{m,\theta} \sqcup W_{n;\text{vert}}^{m,\theta} = W_{n;\text{sur}}^{m,\theta} \]
The proof of the desired equality will lean on a non-stationary phase argument:

Lemma 5.7. Suppose that \( \psi \in H \) satisfies
\[ \chi(-b^2x^2)(H)\psi = \psi \]
for some \( b > 0 \). Fix \( v > 0 \) and \( m > 1 \). For any \( \theta \) such that \( \sin(\theta) < \frac{v}{4b} \) and \( \delta < \frac{v}{8} \)
\[ \| P_\delta(W_{n;\text{vert}}^{m,\theta}) e^{-it_nH} \psi \| \overset{n \to \infty}{\to} 0 \]
where \( t_n = \frac{n}{v} \).
Proof. This proof is similar to the proof of Lemma 4.8. Similarly to the proof of Theorem 4.1, choose \( \Phi \) continuous so that \( \Phi(x) = 0 \) for \( |x| > 4b^2 \) and \( \Phi(x) = 1 \) for \( |x| < b^2 \).

We now write

\[
W_{n,\theta}^{m,\theta} = W_{n,\theta} \sqcup W_{n,\theta}^c
\]

where

\[
W_{n,\theta}^b = \{(x, p) \in \mathbb{R}^d \mid x \in A_{n,m} \land p \in C_\theta \cap B_{2b+\delta}\}
\]

\[
W_{n,\theta}^c = \{(x, p) \in \mathbb{R}^d \mid x \in A_{n,m} \land p \in C_\theta \cap B_{2b+\delta}\}
\]

For any state \( \varphi \), the Fourier support of \( \Phi(H_0)\varphi \) is contained in \( B_{2b} \) so by Proposition A.6, \( \Phi(H_0) = 0 \). Therefore,

\[
\|P_\delta(W_{n,\theta}^c)e^{-itnH}\varphi\| \leq \|P_\delta(W_{n,\theta}^c)(1 - \Phi(H))e^{-itnH}\varphi\| + \|P_\delta(W_{n,\theta}^c)(\Phi(H) - \Phi(H_0))e^{-itnH}\varphi\| + \|P_\delta(W_{n,\theta}^c)e^{-itnH}\varphi\|
\]

with the first and last summands are 0 by the energy support of \( \psi \) and the above claim. Furthermore, by Lemma 4.2, the second summand goes to 0 as well as \( n \to \infty \).

We now write

\[
\|P_\delta(W_{n,\theta}^{m,\theta})e^{-itnH}\varphi\| \leq \|P_\delta(W_{n,\theta}^c)(e^{-itnH} - e^{-itnH_0})\varphi\| + \|P_\delta(W_{n,\theta})e^{-itnH_0}\varphi\| + \|P_\delta(W_{n,\theta}^c)e^{-itnH}\varphi\|
\]

so it suffices to prove that

\[
\|P_\delta(W_{n,\theta})(e^{-itnH} - e^{-itnH_0})\|_{op} \overset{n \to \infty}{\longrightarrow} 0 \tag{5.3.1}
\]

and

\[
\mathbf{s-lim}_{n \to \infty} P_\delta(W_{n,\theta})e^{-itnH_0} = 0 \tag{5.3.2}
\]

As before, both claims will follow from an estimate on the free propagation \( e^{-itH_0} \).

Claim 5.8. With all parameters as above, for any \( R > 0 \) and \( \ell > 0 \), there exists \( C > 0 \), independent of \( n, m, \) and \( v \) such that

\[
\|\chi_{S_R}e^{-itH_0}P_\delta(W_{n,\theta})\|_{op} \leq \frac{Cm^k}{v}n^{-\ell} \tag{5.3.3}
\]

for all \( n > 4R \).

Proof. From Proposition A.5, we have that

\[
\|\chi_{S_R}e^{-itnH_0}P_\delta(W_{n,\theta})\|_{op} \leq (2\pi)^{-d} \int_{W_{n,\theta}} \|\chi_{S_R}e^{-itnH_0}\xi_{x,p,\theta}\|^2 \, dx \, dp \tag{5.3.4}
\]

Let \( (x, p) \in W_{n,\theta}, y \in S_R, \) and \( \xi \in \mathcal{O} := \text{supp } \eta_{x,p,\theta} + B_\delta \). Since \( \xi \in \mathcal{O} \), we may write \( \xi = p + p' \), where \( p \in C_\theta \cap B_{2b+\delta}, p' \in B_{2\delta} \), which implies

\[
\|\xi\|^2 \leq \|p\|^2 + 2\delta \leq \|p\|\sin(\theta) + 2\delta \leq b\sin(\theta) + 2\delta
\]

\[
\leq \frac{2v}{4} = \frac{v}{2}
\]
and therefore
\[ \| \xi^t \| \leq \frac{n}{2} \]
It follows that
\[ \| x^t + \xi^t - y^t \| \geq \| x^t \| - \| y^t \| \geq \| x^t \| - R - \frac{n}{2} \geq \frac{1}{8}(\| x^t \| + n) \]
where we have used that \( \| x^t \| > n > 4R > \| y^t \| \). In total, we obtain an estimate of the form
\[ \| x + t_n \xi - y \| \geq (\| x^t \| + t_n \xi^t - y^t \|^2 + C(\| x^t \| + n)^2)^{\frac{1}{2}} \]
so by comparison to (4.10.7), we may prove the claim as in the conclusion of Lemma 4.4, using in particular that \( W_{n,b} \) has compact support in the momentum coordinate.

Given this claim, it is easy to see that the lemma follows from the argument proving Lemma 4.8.

**Proposition 5.9.**

\[ \mathcal{H}_{\text{sur}} = \tilde{\mathcal{H}}_{\text{sur}} \]

**Proof.** We will start with showing that \( \tilde{\mathcal{H}}_{\text{sur}} \subset \mathcal{H}_{\text{sur}} \).

By density it suffices to consider \( \psi \in \mathcal{H}_{\text{sur}} \) such that \( \chi_{(-\delta^2,\delta^2)}(H)\psi = \psi \) for some \( \delta > 0 \). Fix \( \nu > 0 \) and any \( m > 1 \). Now choose \( \delta \) so that \( \sin(\delta) \leq \nu \). Since \( \psi \in \mathcal{H}_{\text{sur}} \) we know that for these values of \( m \) and \( \theta \)
\[ \limsup_{\delta \to 0} \limsup_{n \to \infty} \limsup_{t \geq 0} \| P_\delta(W_{m;{\text{far}}}e^{-i\nu t} \psi) \| = 0 \]
Thus for any \( \epsilon > 0 \) there is some \( \delta_0 = \delta_0(m) > 0 \) such that
\[ \forall \delta < \delta_0, \limsup_{t \to \infty} \limsup_{\tau \geq 0} \| P_\delta(W_{m;{\text{far}}}e^{-i\nu t - i\tau} \psi) \| < \epsilon \]
Now choose \( \delta < \min(\nu, \delta_0) \) and note that for any \( t > 0 \)
\[ \| \psi \| \leq \| P_\delta(W_{m;{\text{far}}}e^{-i\nu t} \psi) \| + \| P_\delta(W_{m;{\text{close}}}e^{-i\nu t} \psi) \| + \| P_\delta(W_{m;{\text{vert}}}e^{-i\nu t} \psi) \| \]
\[ \leq \sup_{\tau \geq 0} \| P_\delta(W_{m;{\text{far}}}e^{-i\nu t - i\tau} \psi) \| + \| P_\delta(W_{m;{\text{close}}}e^{-i\nu t - i\tau} \psi) \| + \| P_\delta(W_{m;{\text{vert}}}e^{-i\nu t - i\tau} \psi) \| \]
Taking a lim sup as \( t \to \infty \), from Claim 5.7, we see that
\[ \| \psi \| \leq \epsilon + \limsup_{t \to \infty} \| P_\delta(W_{m;{\text{close}}}e^{-i\nu t} \psi) \| \]
Furthermore, since \( W_{m;{\text{close}}} = A_{n,m} \times \mathbb{R}^d \), by Proposition A.3
\[ \| P_\delta(W_{m;{\text{close}}}e^{-i\nu t} \psi) \| = \| (\eta_{\delta} \ast \chi_{A_{n,m}}) e^{-i\nu t} \psi \| \]
\[ \leq \| (\eta_{\delta} \ast \chi_{A_{n,m}}) \chi_{A_{2n,m}} e^{-i\nu t} \psi \| + \| (\eta_{\delta} \ast \chi_{A_{n,m}}) \chi_{A_{2n,m}} e^{-i\nu t} \psi \| \]
\[ \leq \| \chi_{A_{2n,m}} e^{-i\nu t} \| + \| (\eta_{\delta} \ast \chi_{A_{n,m}}) \chi_{A_{2n,m}} \| \| \psi \| \]

Taking the $\limsup$ on both sides, since $\delta$ is fixed, we get that
\[
\limsup_{t \to \infty} \| P_t(\omega_{x,m}^\beta) e^{-itH} \psi \| \leq \limsup_{t \to \infty} \| \chi_{A_{x,m}} e^{-itH} \psi \|
\]
as \[
\| (\eta \ast \chi_{A_{x,m}}) \chi_{A_{x,m}} \|_\infty t \to \infty 0 \text{ (see the proof of Proposition A.7)}.
\]
So we conclude that for any $v > 0$ and $\epsilon > 0$
\[
\| \psi \| \leq \epsilon + \limsup_{t \to \infty} \| \chi_{A_{x,m}} e^{-itH} \psi \| \leq \| \psi \| + \epsilon
\]
and by taking $\epsilon \to 0$ it follows that
\[
\forall v > 0, \limsup_{t \to \infty} \| \chi_{A_{x,m}} e^{-itH} \psi \| = \| \psi \|.
\]
To complete the proof, we will show that $H_{su_r} \perp \text{Ran}(\Omega^-)$ to see that $H_{su_r} \subset \tilde{H}_{su_r}$. In fact, we will show that $H_{su_r} \perp \Omega^- (D_{x,y})$ for any $x > 0, y \in (0, \frac{r}{2})$ and conclude by density.

Let $\psi \in H_{su_r}, \varphi \in \Omega^- (D_{x,y})$. Choose $v < 2x$ and $m$ such that $A_{x,m} \subset C_{x} \cup B_{2at}$. Now we have
\[
\forall t > 0, \| \chi_{A_{x,m}} e^{-itH} \psi \|^2 = \| \psi \|^2 - \| \chi_{A_{x,m}} e^{-itH} \psi \|^2
\]
\[
\liminf_{t \to \infty} \| \chi_{A_{x,m}} e^{-itH} \psi \|^2 = \| \psi \|^2 - \limsup_{t \to \infty} \| \chi_{A_{x,m}} e^{-itH} \psi \|^2 = 0 \quad (5.3.5)
\]
So we can write, for any $v > 0$ and any $t > 0$
\[
| \langle \psi, \varphi \rangle | \leq | \langle \chi_{A_{x,m}} e^{-itH} \psi, e^{-itH} \varphi \rangle | + | \langle e^{-itH} \psi, \chi_{A_{x,m}} e^{-itH} \varphi \rangle |
\]
\[
\leq \| \chi_{A_{x,m}} e^{-itH} \psi \| \| \varphi \| + \| \psi \| \| \chi_{A_{x,m}} e^{-itH} \varphi \|
\]
and then taking a $\liminf$ as $t \to \infty$
\[
| \langle \psi, \varphi \rangle | \leq \liminf_{t \to \infty} [\| \chi_{A_{x,m}} e^{-itH} \psi \| \| \varphi \| + \| \psi \| \| \chi_{A_{x,m}} e^{-itH} \varphi \|] \quad (5.3.6)
\]
Now, since $\varphi \in \Omega^- (D_{x,y})$, there is some $\tilde{\varphi} \in D_{x,y}$ such that
\[
\| e^{-itH} \varphi - e^{-itH} \tilde{\varphi} \| \to 0 \quad (t \to \infty)
\]
Next we recall that we have shown in the proof of Claim 5.3 that for $\tilde{\varphi} \in D_{x,y}$ we have that, that:
\[
x \in \chi_{A_{x,m}} \subset C_{y} \cup B_{2at} \quad \implies \quad \frac{x}{t} \notin \{ 2\xi \mid \xi \in \text{supp} \tilde{\varphi} \}
\]
since supp $\tilde{\varphi} \subset C_{y} \cap B_{2at}$. So we get that for any $\ell > 0$
\[
\| \chi_{A_{x,m}} e^{-itH_0} \tilde{\varphi} \|^2 \leq C \int_{A_{x,m}} (1 + \| x \| + t)^{-\ell} dx
\]
where $C$ does not depend $t$. And in particular, for $\ell$ large enough
\[
\| \chi_{A_{x,m}} e^{-itH_0} \tilde{\varphi} \|^2 \leq C \int_{A_{x,m}} (1 + \| x \| + t)^{-\ell} dx \leq C(1 + t)^{-\ell + d} \to 0 \quad (t \to \infty)
\]
So we can conclude that
\[
\| \chi_{A_{x,m}} e^{-itH} \tilde{\varphi} \| \to 0 \quad (t \to \infty)
\]
Applying this to inequality (5.3.6) combined with equation (5.3.5) we conclude that

\[ |\langle \psi, \varphi \rangle| = 0 \]

which completes the proof. □

This proposition with Lemma 5.2 prove part (ii) of Theorem 1.1. □

6. Examples

Having established our main theorem, we analyze a few special cases to see some of the variety of surface states that may occur. For this purpose, it will be convenient to work with the sufficient condition for being a surface state given in the following proposition.

**Proposition 6.1.** In the notation of Section 7

\[ \mathcal{H}_{\text{sur}}' \subset \mathcal{H}_{\text{sur}} \]

**Proof.** Recall the definition of \( \mathcal{H}_{\text{sur}}' \):

\[ \mathcal{H}_{\text{sur}}'(H) = \{ \psi \mid \lim_{R \to \infty} \sup_{\tau \geq 0} \| \chi_{S_R} e^{-itH} \psi \| = 0 \} \]

We note that for any \( v, m > 0 \), \( \psi \in \mathcal{H} \) and any \( t > 0 \) we have

\[ \| \chi_A e^{-itH} \psi \| \leq \sup_{\tau \geq 0} \| \chi_A e^{-i\tau H} \psi \| \leq \sup_{\tau \geq 0} \| \chi_{S_c} e^{-i\tau H} \psi \| \]

Since this is true for any \( t > 0 \) we can take \( \lim \inf \) on both side to get

\[ \lim_{t \to \infty} \| \chi_A e^{-itH} \psi \| \leq \lim_{t \to \infty} \sup_{\tau \geq 0} \| \chi_{S_c} e^{-i\tau H} \psi \| = \lim_{R \to \infty} \sup_{\tau \geq 0} \| \chi_{S_R} e^{-i\tau H} \psi \| \]

So if \( \psi \in \mathcal{H}_{\text{sur}}' \), the last term is 0, and therefore \( \psi \in \mathcal{H}_{\text{sur}} \), as needed. □

6.1. Surface States in \( \sigma_c(H) \). While it is clear from the above proposition that eigenfunctions of \( H \) are surface states, it is natural to ask whether there may also be surface states in the continuous subspace. We answer this in the affirmative via a simple example.

Let \( d = 2 \) and consider a potential which depends on the \( x \) coordinate only:

\[ V(x, y) = V_0(x) \]

\[ \text{supp } V_0 \subset \{ |x| < 1 \} \]

Then we may write

\[ H := -\frac{\partial^2}{\partial x^2} - \frac{\partial^2}{\partial y^2} + V(x, y) = H_x \otimes \text{id} + \text{id} \otimes H_y \]

where \( H_x \) and \( H_y \) are the one-dimensional operators

\[ H_x = -\frac{d^2}{dx^2} + V_0(x) \]

\[ H_y = -\frac{d^2}{dy^2} \]

Assume that \( H_x \) has an eigenvalue \( E_0 \) with corresponding eigenfunction \( \psi_0 \). For any \( \psi_1(y) \in L^2(\mathbb{R}) \), we claim that

\[ \varphi(x, y) := \psi_0(x) \psi_1(y) \quad (6.1.1) \]
is in $\mathcal{H}_{\text{sur}}(H)$.
To see this, note that since $H = H_x \otimes \text{id} + \text{id} \otimes H_y$ we may write
\[ e^{-itH}\varphi = e^{-itH_x}\psi_0 \otimes e^{-itH_y}\psi_1 = e^{-itE_0}\psi_0 \otimes e^{-itH_y}\psi_1 \]
so that for all $t$
\[ \|X_n e^{-itH}\varphi\|_2^2 = \int_{\mathbb{R}} \int_{|x| > n} |e^{-itE_0}\psi_0(x)e^{-itH_y}\psi_1(y)|^2 \, dx \, dy \]
\[ = \int_{\mathbb{R}} |e^{-itH_y}\psi_1(y)|^2 \, dy \int_{|x| > n} |e^{-itE_0}\psi_0(x)|^2 \, dx = \|e^{-itH_y}\psi_1\|_2^2 \int_{|x| > n} |\psi_0(x)|^2 \, dx \xrightarrow{n \to \infty} 0 \]
Therefore, by Proposition 6.1 we conclude that $\varphi \in \mathcal{H}_{\text{sur}}$.
Furthermore, if $\psi_1 \in \mathcal{H}_{\text{ac}}(H_y)$, as $H_y$ is purely ac, we can guarantee that $\varphi \in \mathcal{H}_{\text{ac}}(H)$. This is because for self-adjoint operators of the form $D = A \otimes \text{id} + \text{id} \otimes B$, the spectral measure of $f(x)g(y)$ with respect to $D$ is given by the convolution of the spectral measure of $f$ with respect to $A$ with the spectral measure of $g$ with respect to $B$ (see [12] for more details).

**Remark.** In [23], Richard generalized this example by introducing a class of “Cartesian potentials” that, roughly speaking, attain different limits in different coordinate directions. For instance, we may consider potentials of the form $V(x, y) = V_0(x)V_1(y)$, where $V_0(x)$ is as above and $V_1(y)$ decays to a limit in a short-range way: there exists some $c \in \mathbb{R}$ such that
\[ \|\chi(|y| > R)(V_1(y) - c)\|_{\text{op}} \in L^1(R) \]
Writing
\[ H_1 = -\Delta + cV_0(x) \]
\[ H_x = -\frac{d^2}{dx^2} + cV_0(x) \]
one may infer from Theorem 1.2 in [23] that
\[ \mathcal{H} = \text{Ran}(\Omega^-) \oplus \mathcal{H}_{pp}(H) \oplus \text{Ran}(\tilde{\Omega}^-) \]
where
\[ \tilde{\Omega}^- = \text{s-lim}_{t \to \infty} e^{itH} e^{-itH_1} (\text{id} \otimes P_{\mathcal{H}_{pp}}(H_x)) \]
By an argument similar to the one given for the above example, it is easy to see that $\text{Ran}(\tilde{\Omega}^-) \subset \mathcal{H}'_{\text{sur}}$ so that $\mathcal{H}'_{\text{sur}} = \mathcal{H}_{\text{sur}}$.

**6.2. Potentials Periodic in All But One Direction.** Now suppose that $k = d - 1$ and that $V$ is periodic in all but one direction in that there are linearly independent vectors $a_1, \ldots, a_{d-1} \subset \mathbb{R}^d$ such that $V(x + a_i) = V(x)$ for all $i$ and $x \in \mathbb{R}^d$. The additional structure of such potentials allows us to give a simpler characterization of the surface states. The proof below can be gleaned from the analysis of such systems in [7], but we include a proof for the sake of completeness. A similar proof for a different system may be found in [25].

**Theorem 6.2.** Suppose that $V$ is periodic in all but one direction. Then
\[ \mathcal{H} = \text{Ran} \Omega^- \oplus \mathcal{H}'_{\text{sur}} \]
In particular, $\mathcal{H}'_{\text{sur}} = \mathcal{H}_{\text{sur}}$. 

Proof. Following [7], there exists $U : \mathcal{H} \to \int_T^{\oplus} \mathcal{H}(\theta) \ d\theta$ unitary that partially diagonalizes $H$. Here, $T := [0, 2\pi)^{d-1}$ and $\mathcal{H}(\theta) = L^2(D)$ for

$$D = \{ x \in \mathbb{R}^{d-1} \mid x = \sum_{i=1}^{d-1} a_i y_i \text{ for } y \in [0, 1)^{d-1} \} \times \mathbb{R}$$

is the cylinder over the basic cell of the periods. For each $\theta$, we let $H_0(\theta)$ be $-\Delta$ on $\mathcal{H}(\theta)$ with core given by $\psi \in L^2(D)$ with smooth extensions to $\mathbb{R}^d$ satisfying $\psi(x + a_j) = e^{i\theta_j} \psi(x)$ for all $j$ and $x \in \mathbb{R}^d$. Letting $H(\theta) = H_0(\theta) + V$, we have the unitary equivalence

$$U H U^* = \int_T H(\theta) \ d\theta$$

These properties of the direct integral decomposition for periodic operators are enough to prove Theorem 6.2. We refer the interested reader to [22] for more details about this decomposition.

From Theorem 5.2 of [26], for all $\theta \in T$ the wave operators

$$\Omega^\pm(\theta) := \lim_{t \to \pm \infty} e^{-itH(\theta)} e^{-itH_0(\theta)} P_{\text{ac}}(H_0(\theta))$$

exist and are complete in the sense that

$$\text{Ran} \ \Omega^+(\theta) = \text{Ran} \ \Omega^-(\theta) = \mathcal{H}_{\text{ac}}(H(\theta))$$

and $H(\theta)$ has no singular continuous spectrum. Therefore, for each $\theta$,

$$\mathcal{H}(\theta) = \text{Ran} \ \Omega^-(\theta) \oplus \mathcal{H}_{\text{pp}}(H(\theta))$$

so that

$$\mathcal{H} = U^* \int_T \text{Ran} \ \Omega^-(\theta) \ d\theta \oplus \mathcal{H}_s$$

where $\mathcal{H}_s := \int_T \mathcal{H}_{\text{pp}}(H(\theta)) \ d\theta$. These direct integrals are well-defined because $\theta \mapsto \Omega^-(\theta)$ and $\theta \mapsto P_{\text{pp}}(H(\theta))$ are measurable - see the Appendix to [7].

Following the proof of Theorem 1.8 in [13], Theorem XII.85 of [22] implies that

$$U e^{-itH} U^* = \int_T e^{-itH(\theta)} \ d\theta \quad U e^{-itH_0} U^* = \int_T e^{-itH_0(\theta)} \ d\theta$$

Thus, for any $\psi \in L^2(\mathbb{R}^d)$

$$\|U e^{itH} e^{-itH_0} \psi - \int_T \Omega^\pm(\theta) U \psi \|^2 =$$

$$\int_T \int_D \| e^{itH(\theta)} e^{-itH_0(\theta)} (U \psi)(\theta, x) - \Omega^\pm(\theta)(U \psi)(\theta, x) \|^2 \ dx \ d\theta$$

The inner integral goes to 0 as $t \to \pm \infty$ since $\Omega^\pm(\theta)$ exists so that by the dominated convergence theorem, we see that $\Omega^\pm = U \int_T \Omega^\pm(\theta) \ d\theta U^*$. It follows that $\mathcal{H} = \text{Ran} \ \Omega^- \oplus \mathcal{H}_s$. 

Furthermore, Proposition 6.1 of [7] shows that $\mathcal{H}_s \subset \mathcal{H}'_{\text{sur}}$ and it is clear that $\text{Ran} \Omega^- \subset (\mathcal{H}'_{\text{sur}})\perp$ because from part (ii) of Theorem 1.1 $\text{Ran} \Omega^- = (\mathcal{H}_{\text{sur}})\perp$ and $\mathcal{H}'_{\text{sur}} \subset \mathcal{H}_{\text{sur}}$ from Proposition 6.1. Therefore,

$$\mathcal{H} = \text{Ran} \Omega^- \oplus \mathcal{H}_s \subset (\mathcal{H}'_{\text{sur}})\perp \oplus \mathcal{H}'_{\text{sur}}$$

which is only possible if in fact $\mathcal{H} = \text{Ran} \Omega^- \oplus \mathcal{H}'_{\text{sur}}$. Since we have proven that in general $\mathcal{H}_{\text{sur}}$ is the orthogonal complement of $\text{Ran} \Omega^-$, we see that $\mathcal{H}'_{\text{sur}} = \mathcal{H}_{\text{sur}}$. □

6.3. **Small surface perturbations.** For a potential that is small enough in the appropriate sense, one would expect that there should be no non-trivial surface states, as is the case for $H_0$. Indeed, this holds for $k \geq 3$ from a result in [8]:

**Theorem 6.3** (Cor. 2.1 from [8]). For $V$ $\Delta$-bounded with relative bound less than one, assume that there exists some constants $C \leq \frac{(k-2)^2}{2}$ and $C' > 0$ such that

1. $|D^\perp V(x)| \leq \frac{C}{|x|^2}$.
2. $|D^\perp D^\perp V(x)| \leq \frac{C'}{|x|^2}$.
3. $|V(x)| \leq \frac{C'}{|x|^2}$.
4. $\|D^\perp V\|_{L^2 \to H^2} < \infty$

where $D^\perp = \sum_{j=1}^k x_j \frac{\partial}{\partial x_j}$ and $H^2$ is the Sobolev space of order two. Then the wave operators $\Omega^\pm$ exist and define a unitary equivalence between $\mathcal{H}$ and $H_0$.

The condition (1) implies that outside of a compact neighborhood of the origin, $V(x)$ must be bounded by some dimensional constant. Therefore, the above conditions may be regarded as imposing some sort of smallness on $V$.

6.4. **Random surface potentials.** In this section, we summarize some results from [9] which show that almost surely $\mathcal{H}_{\text{sur}}$ is infinite dimensional for certain classes of random surface potentials. To this end, let

$$H(\omega) = H_0 + V_\omega$$

be the random operator on $\mathbb{R}^d$ given by the potential

$$V_\omega = \sum_{k \in \mathbb{Z}^d} q_k(\omega) f(x - (k, 0))$$

where $f$, the single site potential satisfies

1. $f \geq 0$ and $f > \sigma > 0$ on some non-empty open set.
2. $f \in L^p(\mathbb{R}^d)$ for $p \geq 2$ if $d \leq 3$ and $p > \frac{d}{2}$ if $d > 3$.

and the random coefficients $q_k$ satisfy

1. The $q_k(\omega)$ are i.i.d. random variables with distribution given by a measure $\mu$ such that $\text{supp} \mu = [q_{\text{min}}, 0]$ for some $q_{\text{min}} < 0$.
2. $\mu$ is Hölder continuous.
3. There exist $C, \tau > 0$ such that for all $\varepsilon > 0$

$$\mu([q_{\text{min}}, q_{\text{min}} + \varepsilon]) \leq C\varepsilon^\tau$$
One can show that almost surely $\sigma(H(\omega)) = [E_0, \infty)$ where

$$E_0 = \inf \sigma(H_0 + q_{\min} \sum_{k \in \mathbb{Z}^d} f(x - (k,0)))$$

which is negative. Under these assumptions we have that

**Theorem 6.4** (Theorem 1.2 in [9]). For $H(\omega)$ as above, there exists $\varepsilon > 0$ such that the spectrum of $H(\omega)$ is almost surely pure point in the interval $[E_0, E_0 + \varepsilon]$.

Because eigenfunctions are clearly surface states, for instance by Proposition 6.1, this demonstrates that random models can induce an infinite dimensional space of surface states.

**Appendix A. Properties of Phase Space Observables**

In this appendix we prove several properties of the phase space observables $P_\delta(E)$ that we use above.

**Proposition A.1.** We have the following equality:

$$(2\pi)^{-d} \int_{\mathbb{R}^d} |\langle \eta_{x,p;\delta}, \psi \rangle|^2 dp = \int_{\mathbb{R}^d} |\bar{\eta}_\delta(y - x)\psi(y)|^2 dy$$

**Proof.** If we denote by $\mathcal{F}(\cdot)$ the Fourier transform then

$$(2\pi)^{-d/2} \langle \eta_{x,p;\delta}, \psi \rangle = (2\pi)^{-d/2} \int_{\mathbb{R}^d} e^{-ip(y-x)}\bar{\eta}_\delta(y-x)\psi(y) dy = e^{ipx}\mathcal{F}(\bar{\eta}_\delta(\cdot - x)\psi(\cdot))(p)$$

So, the proposition follows directly from Plancherel:

$$(2\pi)^{-d} \int_{\mathbb{R}^d} |\langle \eta_{x,p;\delta}, \psi \rangle|^2 dp = \int_{\mathbb{R}^d} |e^{ipx}\mathcal{F}(\bar{\eta}_\delta(\cdot - x)\psi(\cdot))(p)|^2 dp = \int_{\mathbb{R}^d} |\bar{\eta}_\delta(y - x)\psi(y)|^2 dy$$

as needed. \hfill \Box

**Corollary A.2.** For any $\delta > 0$

$$P_\delta(\mathbb{R}^{2d}) = \text{id}$$

**Proof.** This is a direct application of the above:

$$\langle \psi, P_\delta(\mathbb{R}^{2d})\psi \rangle = (2\pi)^{-d} \int_{\mathbb{R}^d} \int_{\mathbb{R}^d} |\langle \eta_{x,p;\delta}, \psi \rangle|^2 dx dp = \int_{\mathbb{R}^d} \int_{\mathbb{R}^d} |\bar{\eta}_\delta(y - x)\psi(y)|^2 dx dy$$

$$= \|\eta_\delta\|^2 \|\psi\|^2 = \|\psi\|^2$$

from which it follows that $P_\delta(\mathbb{R}^{2d}) = \text{id}$ because a self-adjoint operator is determined by its diagonal matrix elements. \hfill \Box

**Corollary A.3.** For $A \subset \mathbb{R}^d$ let $E = A \times \mathbb{R}^d$. Then for any $\delta > 0$ and $\psi \in \mathcal{S}$

$$(P_\delta(E)\psi)(y) = [(|\eta_\delta|^2 * \chi_A)\psi](y)$$
Proof. This is also a direct application:

\[
\langle \psi, P_\delta(E)\psi \rangle = \int_A \int_{\mathbb{R}^d} |\langle \eta_{x,p,\delta}, \psi \rangle|^2 \, dp \, dx = \int_A \int_{\mathbb{R}^d} |\eta_{y-x}(y)|^2 \, dy \, dx
\]

\[
= \int_{\mathbb{R}^d} (|\eta_\delta|^2 \ast \chi_A)(y) |\psi(y)|^2 \, dy
\]

from which the claim follows. \(\square\)

**Proposition A.4.** For each \(E \subset \mathbb{R}^{2d}\) Borel, \(0 \leq P_\delta(E) \leq \text{id}\). In particular

\[
\|P_\delta(E)\|_{\text{op}} \leq 1
\]

**Proof.**

\[
0 \leq \langle \psi, P_\delta(E)\psi \rangle = (2\pi)^{-d} \int_E |\langle \eta_{x,p,\delta}, \psi \rangle|^2 \, dx \, dp \leq (2\pi)^{-d} \int_{\mathbb{R}^{2d}} |\langle \eta_{x,p,\delta}, \psi \rangle|^2 \, dx \, dp = \|\psi\|^2
\]

The operator norm bound comes from the fact that for a self-adjoint operator \(A\)

\[
\|A\|_{\text{op}} = \sup_{\|\psi\|=1} |\langle \psi, A\psi \rangle|
\]

from which the claim is immediate. \(\square\)

Next we want to be able to bound the operator norm of \(AP_\delta(E)\) for another operator \(A\):

**Proposition A.5.** For any \(\delta > 0\), and \(A\) any operator we have:

\[
\|AP_\delta(E)\|_{\text{op}}^2 \leq (2\pi)^{-d} \int_E \|A\eta_{x,p,\delta}\|^2 \, dx \, dp
\]

**Proof.**

\[
\|AP_\delta(E)\psi\|^2 = (2\pi)^{-2d} \int_{\mathbb{R}^d} \int_{\mathbb{R}^{2d}} |\langle \eta_{x,p,\delta}, \psi \rangle A\eta_{x,p,\delta}(y)\, dx \, dp|^2 \, dy \\
\leq (2\pi)^{-2d} \int_{\mathbb{R}^d} \int_{\mathbb{R}^{2d}} |\langle \eta_{x,p,\delta}, \psi \rangle|^2 \, dx \, dp \int_{\mathbb{R}^d} |A\eta_{x,p,\delta}(y)|^2 \, dx \, dp \, dy \\
= (2\pi)^{-d} \|\psi\|^2 \int_{\mathbb{R}^d} \|A\eta_{x,p,\delta}\|^2 \, dx \, dp
\]

as needed. \(\square\)

**Proposition A.6.** Let \(\psi \in \mathcal{H}\) be such that \(\text{supp} \hat{\psi} \subset D\) and let \(E \subset \mathbb{R}^d \times B\) Borel where \(B \subset \mathbb{R}^d\) satisfies \(d(D, B) \geq \delta\). Then

\[
P_\delta(E)\psi = 0
\]

Furthermore, if \(F \subset \mathbb{R}^d \times D\) then

\[
P_\frac{\delta}{2}(E)P_\frac{\delta}{2}(F) = 0
\]
\textbf{Proof.} The first equality follows directly from the fact that
\[ \langle \eta_{x,p,\delta}, \psi \rangle = \int_{\mathbb{R}^d} e^{i \xi \cdot \eta_{\delta}^\nu(x-p)} \hat{\psi}(\xi) \, dp = 0 \]
for \( p \in B \) since \( \text{supp} \hat{\eta}_{x,p,\delta} \subset B_\delta + p \).
Similarly, the second equality comes from the fact that for any \( \varphi \in \mathcal{H} \)
\[ \text{supp} \widetilde{P}_\delta(F) \varphi \subset D + B_\delta \]
and an application of the first equality. \( \square \)

\textbf{Proposition A.7.} For any \( \delta > 0 \), and for any Borel set \( D \subset \mathbb{R}^d \), suppose that \( E \subset D \times \mathbb{R}^d \)
is a Borel set. Then for any \( \varphi \in \mathcal{H} \)
\[ \| P_\delta(E) \varphi \|^2 \leq \| (|\eta_\delta|^2 \ast \chi_D) \varphi \| \| \varphi \| \]  
(A.0.1)

In addition, let \( \{ D_r \}_{r \in \mathbb{R}} \) be a collection of Borel sets such that \( d(D_{2r}, D_r) \xrightarrow{r \to \infty} \infty \). Let \( E_r \subset D_r \times \mathbb{R}^d \) be Borel, then
\[ \lim_{r \to \infty} \| P_\delta(E_{2r}) \varphi \|^2 \leq \| \varphi \| \lim_{r \to \infty} \| \chi_{D_r} \varphi \| \]  
(A.0.2)
\[ \lim_{r \to \infty} \| P_\delta(E_r^c) \varphi \|^2 \leq \| \varphi \| \lim_{r \to \infty} \| \chi_{D_r^c} \varphi \| \]  
(A.0.3)
if in each inequality both limits exist.

\textbf{Proof.} The inequality (A.0.1) is a result of the fact that \( P_\delta^2(E) \leq P_\delta(E) \) (which is easy to establish since \( 0 \leq P_\delta(E) \leq \text{id} \)):
\[ \| P_\delta(E) \varphi \|^2 = \langle P_\delta^2(E) \varphi, \varphi \rangle \leq \langle P_\delta(E) \varphi, \varphi \rangle \leq \langle P_\delta(D \times \mathbb{R}^d) \varphi, \varphi \rangle = \langle (|\eta_\delta|^2 \ast \chi_D) \varphi, \varphi \rangle \leq \| (|\eta_\delta|^2 \ast \chi_D) \varphi \| \| \varphi \| \]

To see the limit (A.0.2), first apply the previous inequality to see that
\[ \| P_\delta(E_{2r}) \varphi \|^2 \leq \| (|\eta_\delta|^2 \ast \chi_{D_{2r}}) \varphi \| \| \varphi \| \leq \| \varphi \| \| (|\eta_\delta|^2 \ast \chi_{D_{2r}}) \chi_{D_r} \varphi \| + \| (|\eta_\delta|^2 \ast \chi_{D_{2r}}) \chi_{D_r^c} \varphi \| \]
\[ \leq \| \varphi \| \| \chi_{D_r} \varphi \| + \| \varphi \|^2 \| (|\eta_\delta|^2 \ast \chi_{D_{2r}}) \chi_{D_r^c} \varphi \| \infty \]

Note that for \( x \in D_r^c \)
\[ (|\eta_\delta|^2 \ast \chi_{D_{2r}})(x) = \int_{D_{2r}} |\eta_\delta(y-x)|^2 \, dy \leq C \int_{D_{2r}} \| x - y \|^{-\ell} \, dy \leq Cd(x, D_{2r})^{-\ell+d} \]
\[ \leq Cd(D_r^c, D_{2r})^{-\ell+d} \xrightarrow{r \to \infty} 0 \]
for \( \ell \) large enough, therefore:
\[ \| \varphi \|^2 \| (|\eta_\delta|^2 \ast \chi_{D_{2r}}) \chi_{D_r^c} \varphi \|^2 \xrightarrow{r \to \infty} 0 \]
which implies inequality (A.0.2). For the second inequality we write
\[ \| P_\delta(E_r^c) \varphi \|^2 \leq \| (|\eta_\delta|^2 \ast \chi_{D_r^c}) \varphi \| \| \varphi \| \leq \| \varphi \| \| \chi_{D_r^c} \varphi \| + \| \varphi \|^2 \| (|\eta_\delta|^2 \ast \chi_{D_r^c}) \chi_{D_{2r}} \varphi \| \]
and apply a similar argument to see that
\[ \| \varphi \|^2 \| (|\eta_\delta|^2 \ast \chi_{D_r^c}) \chi_{D_{2r}} \varphi \|^2 \xrightarrow{n \to \infty} 0 \]
which concludes the proof. \( \square \)
Appendix B. Potentials that Decay in $x^\perp$

In this appendix, we explain how our proofs may be adjusted to accommodate potentials satisfying

\[ \|V\chi_S\|_{op} \in L^1 \quad \text{(B.0.1)} \]
\[ \sup_{x \in \mathbb{R}^d} |V(x)| = M < \infty \quad \text{(B.0.2)} \]

To see the existence, or part (i) of Theorem 1.1, for such potentials, we fix $\varepsilon \in (0, \frac{2\alpha}{\cot(\beta)})$ and change inequality (3.0.1) so that it reads

\[ \|Ve^{-itH_0}\psi\|^2 \leq \frac{M}{(2\pi)^{\frac{d}{2}}} \int_{S_{\varepsilon t}} |e^{-itH_0}\psi(x)|^2 \, dx + \|V\chi_{S_{\varepsilon t}}\|_{op} \|\psi\|^2 \]

The condition on $\varepsilon$ guarantees that $2\alpha t > \cot(\beta)\varepsilon t$, which allows us to bound the first summand in the above by $C(1 + t)^{-\ell + d}$ for any $\ell > 0$ (compare to inequality (3.0.2)). This, combined with the condition (B.0.1), lets us conclude the existence of the wave operators.

For part (ii) of Theorem 1.1, there are several adjustments to be made. First, in the proof of Lemma 4.2, we replace inequality (4.0.1) with

\[ \|\chi_{A_{n,m}}(H_0 - z)^{-1}V\psi\|^2 \]
\[ \leq \int_{A_{n,m}} \left| \int_{S_{\frac{\varepsilon}{2}}} G_z(y - x)V(y)\psi(y) \, dy \right|^2 \, dx + \|\chi_{A_{n,m}}(H_0 - z)^{-1}\|_{op}^2 \|\chi_{S_{\frac{\varepsilon}{2}}}V\|_{op}^2 \|\psi\|^2 \]

It may be checked that the first summand still goes to 0 with $n$ by a similar computation to the original argument while the second summand goes to 0 with $n$ due to (B.0.1).

The proof of Lemma 4.4 must be modified by fixing $\varepsilon \in (0, \min(\frac{1}{8}, \frac{a}{8} \sin(\theta)))$ and replacing (4.0.4) by

\[ \|(\Omega - \text{id})\varphi_{n;\text{out}}\| \leq M \int_0^\infty \|\chi_{S_{\varepsilon(t+n)}}e^{-itH_0}\varphi_{n;\text{out}}\| \, dt + \int_0^\infty \|V\chi_{S_{\varepsilon(t+n)}}\|_{op} \|\varphi_{n;\text{out}}\| \, dt \]

Again, the second summand decays as per usual. For the first summand, we must only change Claim 4.7 to allow $y \in S_{\varepsilon(t+n)}$, which is achieved via restricting $\frac{\varepsilon}{2} < c$ in Claim 4.6. Similar adjustment will give the result for Lemma 5.7. After this, the proof works as written.
