We study the Quantum Brownian motion of a charged particle moving in a harmonic potential in the presence of an uniform external magnetic field and linearly coupled to an Ohmic bath through momentum variables. We analyse the growth of the mean square displacement of the particle in the classical high temperature domain and in the quantum low temperature domain dominated by zero point fluctuations. We also analyse the Position Response Function and the long time tails of various correlation functions. We notice some distinctive features, different from the usual case of a charged quantum Brownian particle in a magnetic field and linearly coupled to an Ohmic bath via position variables.

I. INTRODUCTION

The Quantum Brownian Motion of a particle undergoing diffusion driven by quantum fluctuations has been the focus of study for some time [1–4]. More recently, researchers have investigated the diffusion behaviour of a charged particle in a magnetic field [5–7]. To study this problem, one considers a Quantum Langevin Equation which corresponds to a reduced description of the system in which the coupling with the heat bath is described by two terms: an operator valued random force $F(t)$ with mean zero and a mean force characterized by a memory function $\mu(t)$ [8]. Moreover, some of the studies have focused on an anomalous form of these couplings within a similar framework of the Quantum Langevin dynamics [9–11]. Although, in most of the literature, one considers a conventional form of coupling between the particle and the bath via position variables [1–7], several authors have also considered the case of such a quantum Brownian particle coupled to the bath variables through momentum coordinates [12–19].

In [19] the authors have derived a Quantum Langevin Equation of a charged particle moving in a harmonic potential in the presence of an uniform external magnetic field and linearly coupled to a quantum heat bath through momentum variables. Here we use the Quantum Langevin Equation derived in [19] as a starting point to analyse the growth of the mean square displacement of the particle in the classical high temperature domain and in the quantum low temperature domain dominated by zero point fluctuations. In addition we analyse the long time tails of various correlation functions.

The outline of the paper is as follows. In Sec II we discuss the Quantum Langevin Formalism and the position correlation function, the mean square displacement, the Position Response Function, the position-velocity correlation function and the velocity autocorrelation function. In Sec III we discuss the long time behaviour of the various correlation functions mentioned in Sec II. In Sec IV we present our results and discussions. Finally we end the paper with some concluding remarks in Sec V. We present details of some of the calculations in the Appendix.

II. QUANTUM LANGEVIN FORMALISM

The Hamiltonian of a charged Brownian particle in the presence of a magnetic field and a harmonic oscillator potential and coupled to a heat bath consisting of $N$ oscillators, via momentum coordinate coupling, is given by [19]:

$$H = \frac{1}{2m} \left( \frac{\vec{p}^2}{c} - \frac{q}{c} \vec{A} \right)^2 + \frac{1}{2} m\omega_0^2 \vec{r}^2 + \sum_{j=1}^{N} \left[ \frac{1}{2m_j} \left( \vec{p}_j - g_j \vec{p} + \frac{g_j q}{c} \vec{A} \right)^2 + \frac{1}{2} m_j \omega_j^2 \vec{q}_j^2 \right]$$ (1)

where, $m$ is the mass of the particle, $\vec{p}$ and $\vec{r}$ are the momentum and position coordinates of the particle respectively. $\omega_0$ is the frequency of the harmonic oscillator potential, $q$ is the charge of the particle, $c$ is the speed of light and $\vec{A}$ is the vector potential pertaining to the magnetic field. Furthermore, $m_j$, $\vec{p}_j$, $\vec{q}_j$, $\omega_j$ denote the heat bath variables corresponding to the mass, momentum, position and frequency of the $j^{th}$ oscillator respectively.

Solving the Heisenberg equations of motion and integrating out the bath degrees of freedom, one can arrive at the Quantum Langevin Equation (QLE) of a quantum particle of charge $q$ moving in a harmonic potential in the presence of an uniform external magnetic field $\vec{B}$ and linearly coupled to a quantum heat bath through momentum variables [19]:

$$m_r \ddot{\vec{r}}(t) + \int \mu(t - t') \dot{\vec{r}}(t') dt' + m_r \omega_0^2 \vec{r}(t) + \mu_d(t) \vec{r}(0) - \frac{q}{c} (\vec{r}(t) \times \vec{B}) = \vec{F}(t)$$ (2)

where, $\mu_d(t)$ is the diagonal part of the memory kernel $\mu$, $\vec{r}(0)$ is the initial position of the particle at $t=0$, $\vec{B}$ is
the applied magnetic field and \( \vec{F}(t) \) is the random force with the following properties:

\[
\langle F_\alpha(t) \rangle = 0
\]  

(3)

and

\[
\frac{1}{2} \langle [F_\alpha(t), F_\beta(0)] \rangle = \frac{\hbar \delta_{\alpha\beta}}{\pi} \int_0^\infty d\omega \text{Re} \mu(\omega) \frac{\omega^3 m_r}{\omega^2 m} \times \coth \left( \frac{\hbar \omega}{2k_B T} \right) e^{-i\omega t} 
\]  

(4)

\[
\langle [F_\alpha(t), F_\beta(0)] \rangle = \frac{2\hbar \delta_{\alpha\beta}}{i\pi} \int_0^\infty d\omega \text{Re} \mu(\omega) \frac{\omega^3 m_r}{\omega^2 m} e^{-i\omega t} 
\]  

(5)

Here \( \alpha, \beta = x, y \) and \( \delta_{\alpha\beta} \) is the Kronecker delta function. and

\[
m_r = m / \left[ 1 + \sum_{j=1}^N \frac{g_j^2 m}{m_j} \right] 
\]  

(6)

with \( g_j \) the coupling strength between the particle and the \( j-th \) bath oscillator.

Now, one can define an effective random force \( \vec{G}(t) \) as follows: \( \vec{G}(t) = \vec{F}(t) - \mu_d(t) \vec{r}(0) \), where \( \vec{G}(t) \) retains all the statistical properties of \( \vec{F}(t) \) [8, 19].

For the Ohmic model, \( \mu_d(t) = \gamma m \delta(t) \) [6, 7].

Using this, Eq.(2) takes the form:

\[
m_r \ddot{r}(t) + m_r \omega^2 \dot{r}(t) + m_r \omega_0^2 \dot{r} - \frac{q}{c} (\ddot{r}(t) \times \vec{B}) = \vec{G}(t) 
\]  

(7)

Taking the Fourier transform of Eq.(7) and separating it into \( x \) and \( y \) components we get:

\[
-m_r \omega^2 x + im \gamma \omega x + m_r \omega_0^2 x - im \omega_\omega y = G_x(\omega) \]  

(8)

\[
-m_r \omega^2 y + im \gamma \omega y + m_r \omega_0^2 y + im \omega_\omega x = G_y(\omega) \]  

(9)

where, \( \omega_c = \frac{qB}{mc} \) and \( G_x(\omega) \) and \( G_y(\omega) \) are the Fourier transforms of \( G_x(t) \) and \( G_y(t) \) respectively.

Solving Eqs.(8) and (9), we get \( x(\omega) \) and \( y(\omega) \) as:

\[
x(\omega) = -\frac{-(m_r \omega_0^2 - m_r \omega^2 + im \omega \gamma)(-G_x) - i\omega \omega_r m(-G_y)}{m^2 \omega_c^2 \omega^2 - (m_r \omega_0^2 - m_r \omega^2 + im \omega \gamma)^2} 
\]  

(10)

\[
y(\omega) = -\frac{-(m_r \omega_0^2 - m_r \omega^2 + im \omega \gamma)(-G_y) - i\omega \omega_r m(-G_x)}{m^2 \omega_c^2 \omega^2 - (m_r \omega_0^2 - m_r \omega^2 + im \omega \gamma)^2} 
\]  

(11)

The position autocorrelation function as defined in Refs.[7, 20] is given by:

\[
C_x(\omega) = \frac{1}{2} \langle \{ x(\omega), x^*(\omega) \} \rangle 
\]  

(12)

\[
C_y(\omega) = \frac{1}{2} \langle \{ y(\omega), y^*(\omega) \} \rangle 
\]  

(13)

Now, we use Eq.(4), Eq.(10-11) and Eq. (12-13) to get \( C_x(\omega) = C_y(\omega) = C(\omega) \) as:

\[
C(\omega) = \left( \frac{\hbar m_r}{\pi \omega_0^2} \right) \omega^3 \left[ \frac{1}{m^2} (\omega_0^2 - \omega^2)^2 + \frac{1}{m^2} \omega^2 (\omega_c^2 + \gamma^2) \right] \coth(\frac{\omega}{\Omega_{th}}) 
\]  

(14)

\[
\Omega_{th} = \frac{2k_B T}{\hbar}
\]

According to the Fluctuation Dissipation Theorem [7],

\[
\frac{1}{4} \frac{C(\omega)}{\coth(\frac{\omega}{\Omega_{th}})} = R''(\omega)
\]  

(15)

where \( R''(\omega) \) is the imaginary part of the Response Function.

In this paper, we study the position autocorrelation function, mean square displacement, response function, position-velocity correlation function and velocity autocorrelation function in the context of a quantum Brownian motion of a charged oscillator in a magnetic field coupled to a bath via momentum coupling.

\( \Box \)

The Mean Square Displacement (M.S.D) is defined by [6]:

\[
M.S.D = 2(C(0) - C(t)) 
\]  

(16)

We can express \( C(t) \) in terms of its Fourier transform.
C(\omega) as follows:

\[ C(t) = \frac{1}{2\pi} \int_{-\infty}^{\infty} C(\omega)e^{-i\omega t}d\omega \]

\[ = \frac{\hbar}{2\pi} \int_{-\infty}^{\infty} R''(\omega) \coth \left( \frac{\omega}{\Omega_{th}} \right) e^{-i\omega t}d\omega \]  \hspace{1cm} (17)

\[ R''(\omega) \] has the following poles in the lower half plane:

\[ p_1 = -\frac{m\omega_c - i\omega_0 \gamma + \sqrt{4m^2 \omega_0^2 + m^2(\omega_c + \gamma)^2}}{2m}, \]
\[ p_2 = -\frac{m\omega_c + i\omega_0 \gamma + \sqrt{4m^2 \omega_0^2 + m^2(\omega_c - \gamma)^2}}{2m}, \]
\[ p_3 = \frac{m\omega_c - i\omega_0 \gamma + \sqrt{4m^2 \omega_0^2 - m^2(\omega_c - \gamma)^2}}{2m}, \]
\[ p_4 = \frac{m\omega_c + i\omega_0 \gamma + \sqrt{4m^2 \omega_0^2 - m^2(\omega_c + \gamma)^2}}{2m}. \]

and \[ \coth \left( \frac{\omega}{\Omega_{th}} \right) \] has poles at \(-i\pi\Omega_{th}), n being any positive integer.

So, using the Cauchy’s Residue Theorem, the position correlation function \(C(t)\) can be calculated by summing over the residues at the poles [2, 20, 23]:

\[ C(t) = C_1(t) + C_2(t) \]  \hspace{1cm} (18)

where,

\[ C_1(t) = (-2\pi i) \sum_{j=1}^{4} (\text{Res}[C(\omega)exp(-i\omega t), p_j]) \]
\[ C_2(t) = (-i\hbar\Omega_{th}) \sum_{n=1}^{\infty} R''(-i\pi n\Omega_{th})exp(-n\pi\Omega_{th}t) \]  \hspace{1cm} (20)

\[ \text{Res}[C(\omega), p_j] \] pertains to the residue of \(C(\omega)\) corresponding to the pole at \(p_j\).

(ii) The Position Response Function \((R(t))\) is calculated from the position autocorrelation, by the application of the Kramers Kronig transformation and the Fluctuation dissipation theorem (15). As already discussed, the imaginary part of the Position Response Function in the frequency domain can be derived from the correlation function using the Fluctuation dissipation theorem (15). So, from Eq.(14) we get \(R''(\omega)\) as:

\[ R''(\omega) = \frac{2m}{\pi\omega_0^3} \omega^3 \left[ \frac{1}{m(\omega_0^2 - \omega^2)^2} + \frac{1}{m^2\omega_0^2(\omega_c^2 + \gamma^2)} \right] \]
\[ \left\{ \frac{m}{m} (\omega_0^2 - \omega^2)^2 + \frac{m}{m} \omega_2 (\omega_c^2 + \gamma^2) \right\}^2 - 4\omega_0^2 \omega_2 (\omega_0^2 - \omega^2)^2 \]  \hspace{1cm} (21)

The real part \((R'(\omega))\) of the Position Response Function can be calculated from the imaginary part \((R''(\omega))\) using the Kramers Kronig relation given by [7, 24]:

\[ R'(\omega) = \frac{1}{\pi} \int_{-\infty}^{\infty} \frac{\omega' R''(\omega)}{(\omega'^2 - \omega^2)} d\omega \]  \hspace{1cm} (22)

Similar to \(C(\omega)\), \(R'(\omega)\) has poles at \(\omega' = p_i\) (for \(i=1,..4\)) and at \(\omega' = \pm \omega\).

The residues at \(\omega' = \omega\) and \(-\omega\) cancel out. Thus \(R'(\omega)\) is derived using the Cauchy’s residue theorem:

\[ R'(\omega) = (-2\pi i) \sum_{j=1}^{4} (\text{Res}[\frac{\omega' R''(\omega)}{\pi(\omega'^2 - \omega_j^2)}, p_j]) \]  \hspace{1cm} (23)

The total Position Response Function is then calculated as:

\[ R(\omega) = R'(\omega) + iR''(\omega) \]  \hspace{1cm} (24)

Then the Position Response Function \(R(t)\) in the time domain is easily derived via the Fourier transform of \(R(\omega)\) obtained from the above formalism:

\[ R(t) = \frac{1}{2\pi} \int_{-\infty}^{\infty} R(\omega)e^{-i\omega t}d\omega \]  \hspace{1cm} (25)

This calculation shows that the response function exhibits an exponential decay from a finite value at \(t=0\), which is distinct from the position coupling case which shows a rise in the response function starting from \(t=0\) and settling to a constant as \(t\) increases.

For the simplest case, one may consider the particle in the absence of a magnetic field, i.e., \(\omega_c = 0\) and the response function works out to be:

\[ R(t) = \left\{ \left[ (m\gamma \omega_p) \cos \left( \frac{\omega_p t}{2m\gamma} \right) + \frac{\omega_p^2 - 2m^2 \omega_c^2}{2m\gamma^2} \sin \left( \frac{\omega_p t}{2m\gamma} \right) \right] \right\} \times \]
\[ \exp \left( \frac{-m\gamma t}{2m\gamma} \right) \]  \hspace{1cm} (26)

where, \(\omega_p = \sqrt{4m^2 \omega_0^2 - m^2\gamma^2}\).

It can be seen from Eq.(26) that, at \(t=0\), \(R(t)\) reduces to \(\frac{\gamma}{\pi m \omega_0^3}\) and we notice a subsequent exponential decay at long times. Interestingly, this form of the Position Response Function is similar to that of the Velocity Response Function that one gets in the case of a coupling to the bath via position variables. It could perhaps be due to the fact that the momentum and the position are related via a time derivative and this leads to the difference that we observe between the two cases (the case of a bath coupled via position variables and the one in which the bath is coupled via momentum variables).

(iii) The Position-Velocity Correlation Function \((C_{x-v}(t))\) is derived from the position autocorrelation function [7]:

\[ C_{p-v}(t) = \frac{d}{dt} C_{x}(t) \]  \hspace{1cm} (27)

In the Fourier space:

\[ C_{p-v}(\omega) = -i\omega C_{x}(\omega) \]  \hspace{1cm} (28)
Using Eqs. (14), (27) and (28):
\[ C_{p-v}(t) = C_{p-v_1}(t) + C_{p-v_2}(t) \]  
(29)

where,
\[ C_{p-v_1}(t) = (-2\pi i) \sum_{j=1}^{4} (\text{Res}[C_{p-v}(\omega)] \exp(-i\omega t), p_j) \]  
(30)

\[ C_{p-v_2}(t) = (i\hbar \pi \Omega_{th}) \sum_{n=1}^{\infty} nR''(\pi n\Omega_{th}) \exp(-n\pi \Omega_{th} t) \]  
(31)

(iv) Similar to the case of the position-velocity correlation function, the Velocity Autocorrelation Function \((C_v)\) is calculated as follows [7]:
\[ C_v(t) = -\frac{d^2}{dt^2} C_x(t) \]  
(32)

In the Fourier space:
\[ C_v(\omega) = \omega^2 C_x(\omega) \]  
(33)

Using Eqs. (14), (32) and (33):
\[ C_v(t) = C_{v_1}(t) + C_{v_2}(t) \]  
(34)

where,
\[ C_{v_1}(t) = (-2\pi i) \sum_{j=1}^{4} (\text{Res}[C_v(\omega)] \exp(-i\omega t), p_j) \]  
(35)

\[ C_{v_2}(t) = (i\hbar \pi \Omega_{th}) \sum_{n=1}^{\infty} n^2 R''(\pi n\Omega_{th}) \exp(-n\pi \Omega_{th} t) \]  
(36)

III. LONG TIME BEHAVIOUR OF THE CORRELATION FUNCTIONS

In this section, we have analyzed the long time behaviour of the correlation functions at finite low temperatures and extended the results to get the behaviour in the zero temperature Quantum regime.

A. Position Autocorrelation Function

As discussed in the previous section, the position autocorrelation function at any temperature is given by Eq. (17). At low temperatures, \(\exp(-\gamma t)\) falls off faster than \(\exp(-n\pi \Omega_{th} t)\) and the long time behaviour of the correlation function is determined by \(C_2(t)\) (see Appendix for details). Therefore, at finite low temperatures at long times we get:
\[ C(t) = C_2(t) = (-i\hbar \Omega_{th}) \sum_{n=1}^{\infty} R''(\pi n\Omega_{th}) \exp(-n\pi \Omega_{th} t) \]  
(37)

Now, expanding the imaginary part of the response function \(R''(\omega)\) in a power series using Eq. (14) and Eq. (15), we get:
\[ R''(\omega) = \frac{\gamma}{\pi m_r \omega_0^3} \omega^3 + \frac{(2m_r^2 \omega_0^2 - m_r^2 (\gamma^2 - 3\omega_c^2)) \gamma}{\pi m_r^3 \omega_0^5} \omega^5 + \frac{(3m_r^4 \omega_0^4 - 4m_r^4 \omega_0^2 \omega_0^2 (\gamma^2 - 3\omega_c^2) + m_r^4 (5\omega_c^2 - 10\omega_c^2 \gamma^2 + 4\gamma^4))}{\pi m_r^6 \omega_0^{12}} \times \frac{\gamma}{\pi \omega_0^3} \omega^3 + \ldots... \]  
(38)

Using the above power series expansion, we obtain from Eq. (37) [2, 20]:
\[ C(t) = -i(\hbar \Omega_{th}) \left[ \frac{\gamma}{\pi m_r \omega_0^3} (-i\pi \Omega_{th})^3 \sum_{n=1}^{\infty} n^3 \exp(-n\pi \Omega_{th} t) + \right. \]
\[ \left. \gamma(2m_r^2 \omega_0^2 - m_r^2 (\gamma^2 - 3\omega_c^2)) (-i\pi \Omega_{th})^5 \sum_{n=1}^{\infty} n^5 \exp(-n\pi \Omega_{th} t) \right] + \ldots... \]  
(39)

At finite temperatures and long times, \(\pi \Omega_{th} t >> 1\) and thus we get an exponential decay of the position autocorrelation function:
\[ C(t) = A_c \exp(-\pi \Omega_{th} t) \]  
(41)

where,
\[ A_c = \frac{\hbar \pi \Omega_{th}^2 \gamma}{mm_r \omega_0^5} - \frac{\hbar \pi \Omega_{th}^4 \gamma(2m_r^2 \omega_0^2 - m_r^2 (\gamma^2 - 3\omega_c^2))}{mm_r^3 \omega_0^{10}} + \ldots... \]  
(42)

In contrast, at \(T \rightarrow 0\), we expand \(e^{\pi \Omega_{th} t}\) as a Taylor series and we get a power law behaviour, similar to the case of a particle coupled to a bath via a position coordinate coupling [2, 20], albeit, with higher power exponents.
\[ C(t) = A_{1c} t^{-4} + A_{2c} t^{-6} + \ldots... \]  
(43)

where,
\[ A_{1c} = \frac{6\gamma}{2\pi^2 mm_r \omega_0^5}, \]
\[ A_{2c} = \frac{-120(2m_r^2 \omega_0^2 - m_r^2 (\gamma^2 - 3\omega_c^2)) \gamma}{2\pi^2 mm_r^3 \omega_0^{10}}. \]

It is evident from Eq. (43) that at long times the position autocorrelation function falls off as \(t^{-4}\), which is faster than the \(t^{-2}\) fall off of the position autocorrelation function of a particle coupled to the heat bath via a position coordinate coupling [20].
B. Position-Velocity Correlation Function

The position-velocity correlation function is calculated using Eq.(27) and the long time behaviour is determined at low temperatures.

At finite temperatures, the position velocity correlation function is derived from Eq.(41):

\[ C_{p-v}(t) = -\pi \Omega_{th} A_{c}(t) \exp[-\pi \Omega_{th} t] \]

where \( A_{p-v}(t) = -\pi \Omega_{th} A_{c}(t) \).

At \( T \to 0 \),

\[ C_{p-v}(t) = A_{1c} t^{-5} + A_{2c} t^{-7} + \ldots \] (45)

where,

\[ A_{1c} = -4A_{1c}, \]
\[ A_{2c} = -6A_{2c}. \]

C. Velocity Autocorrelation Function

The velocity autocorrelation function is calculated using Eq.(32) and the long time behaviour is determined at low temperatures.

At finite temperatures, the velocity autocorrelation function is derived from Eq.(41):

\[ C_{v}(t) = -\pi^{2} \Omega^{2}_{th} A_{c}(t) \exp[-\pi \Omega_{th} t] \]

where, \( A_{c}(t) = -\pi \Omega^{2}_{th} A_{c}(t) \).

At \( T \to 0 \),

\[ C_{v}(t) = A_{1c} t^{-6} + A_{2c} t^{-8} + \ldots \] (47)

where,

\[ A_{1c} = 5A_{1c} = -20A_{1c}, \]
\[ A_{2c} = 7A_{2c} = -42A_{2c} \]

IV. RESULTS AND DISCUSSIONS

In this section, we have plotted and analyzed our results based on the graphical representations of the derived quantities.

In Fig. (1) we have plotted the total response function \( R(t) \) as a function of time for under-damped and over-damped cases. Figs. (2) and (3) display the mean square displacement (MSD) and the correlation functions at a finite temperature and \( T \to 0 \) respectively for various damping regimes.

---

FIG. 1: The response function versus time for \( \omega_{0} = 1, m=1, m_{r} = 0.5 \): (a) \( \omega_{c}=10, \gamma = 2 \); (b) \( \omega_{c}=1.2, \gamma = 10 \);
FIG. 2: The mean square displacement (MSD) and correlation function plots as a function of time at a finite temperature for $\omega_0 = 1$, $m=1$, $m_r=0.5$, $\Omega_{th}=0.03$: (a) MSD for $\omega_c=10$, $\gamma = 2$; (b) MSD for $\omega_c=1.2$, $\gamma = 10$; (c) Position autocorrelation for $\omega_c=10$, $\gamma = 2$; (d) Position autocorrelation for $\omega_c=1.2$, $\gamma = 10$ in log-log scale; (e) Position-velocity correlation for $\omega_c=10$, $\gamma = 2$; (f) Position-velocity correlation for $\omega_c=1.2$, $\gamma = 10$ in log-log scale; (g) Velocity autocorrelation for $\omega_c=10$, $\gamma = 2$; (h) Velocity autocorrelation for $\omega_c=1.2$, $\gamma = 10$ in log-log scale [The orange dashed lines in the plots represent the long time exponential behaviours of the correlation functions].
FIG. 3: The mean square displacement (MSD) and correlation function plots as a function of time at $T \to 0$ for $\omega_0 = 1$, $m=1$, $m_r=0.5$, $\Omega_{th}=10^{-6}$: (a) MSD for $\omega_c=10$, $\gamma = 2$; (b) MSD for $\omega_c=1.2$, $\gamma = 10$; (c) Position autocorrelation for $\omega_c=10$, $\gamma = 2$; (d) Position autocorrelation for $\omega_c=1.2$, $\gamma = 10$; (e) Position-velocity correlation for $\omega_c=10$, $\gamma = 2$; (f) Position-velocity correlation for $\omega_c=1.2$, $\gamma = 10$; (g) Velocity autocorrelation for $\omega_c=10$, $\gamma = 2$; (h) Velocity autocorrelation for $\omega_c=1.2$, $\gamma = 10$ [The orange dashed lines in the plots represent the long time power law behaviours of the correlation functions].
In Fig.(1a), we notice that the Position Response Function in the under-damped regime initially shows an oscillatory behaviour starting from a finite value and then settles to zero with increasing time. On the other hand, the Response Function in the over-damped regime exhibits an exponential decay from $\frac{2\gamma}{\pi m_\nu \omega_0^3}$ at $t=0$. As discussed in the previous section, this kind of behaviour resembles the Velocity Response Function, obtained as the derivative of the Position Response Function for coupling through position coordinate. The sharp contrast stems from the $\omega^3$ dependence of force correlations (see Eq.(5)) in the case of a bath coupled via momentum variables, which is in contrast to the case of a bath coupled via position variables, where the force correlation varies linearly with $\omega$. This kind of a behaviour is expected in the case of a bath coupled via momentum variables since the position and momentum are conjugate variables connected by a time derivative.

One noticeable distinctive feature of the plots of the MSD versus $t$ is the fact that the MSD settles to a constant value ($2C_x(0)$) at long times over the entire range of temperatures. This feature survives even when one removes the harmonic confinement. This is strikingly different from the case of a bath with a position coordinate coupling, where the MSD exhibits a linear behaviour with time in the absence of a harmonic potential (i.e. for $\omega_0 = 0$) and settles to a constant value in the presence of a harmonic confinement (i.e. for a nonzero $\omega_0$) [6]. Similar to the Position Response Function, this behaviour of the MSD is attributed to the decay of position autocorrelation function ($C_x(t)$) to zero, with increasing time, due to the fact that the force correlation (see Eq.(5)) goes as $\omega^3$.

We have also plotted the correlation functions at finite and $T \rightarrow 0$ temperatures and analyzed the long time behaviours of the correlation functions, similar to our previously reported work on the quantum Brownian motion of a particle coupled to a bath via a position coordinate coupling [20]. At finite temperatures, the correlation functions display an exponential decay at long times as discussed in the previous section. However, at $T \rightarrow 0$, we notice a transition from a power law to an exponential behaviour around a time scale set by $\frac{4}{\pi k_B T}$ [2, 20]. This can be clearly seen from the above plots, where, the orange dashed lines in Figs.(1c)-(1h) represent the long time exponential behaviour at finite temperatures, whilst the orange dashed curves in Figs.(2c)-(2h) represent the power law tails at long times for $T \rightarrow 0$. It can be noticed that the $t^{-4}, t^{-5}, t^{-6}$ power law decays of the position autocorrelation function ($C(t)$), position-velocity correlation function ($C_{p,v}(t)$) and velocity autocorrelation function ($C_v(t)$) respectively are sharper compared to the case of a position coordinate coupling ($t^{-2}$ for $C(t)$, $t^{-3}$ for $C_{p,v}(t)$, $t^{-4}$ for $C_v(t)$) [20]. Hence, it can be inferred from the behaviours of the MSD and the correlation functions, that the effect of harmonic confinement is more pronounced for a particle coupled to the heat bath via momentum coordinate coupling. It may also be noted that, the $t^{-4}$ decay of the position autocorrelation function in the case of a coupling to the bath via a momentum coordinate is exactly same as the $t^{-4}$ power law decay of the velocity autocorrelation function in the case of a coupling to the bath via a position coordinate coupling.

V. CONCLUSION

We have derived the mean square displacement, position response function and the position autocorrelation, position-velocity correlation and velocity autocorrelation functions of a charged harmonically confined Quantum Brownian particle in the presence of a magnetic field and attached to a heat bath via a momentum coordinate coupling. There are quite a few studies on the case of a momentum coordinate coupling to a bath of a Quantum Brownian particle [12–19]. Nevertheless, the study of a system coupled to a heat bath via a momentum coordinate coupling still remains a relatively unexplored area in the context of Quantum Brownian motion, in particular in the context of a charged harmonically confined Quantum Brownian particle coupled to a heat bath. In [19] the Quantum Langevin Equation for a charged harmonic oscillator coupled to a heat bath via a momentum coordinate coupling and in the presence of a magnetic field has been derived. We have, however, gone far beyond that and derived the MSD, the position response function and the correlation functions and analyzed their long time behaviours at finite and near zero temperatures.

Here, we notice two distinctive features in the behaviours of the MSD and position response function ($R(t)$), which can be seen in Figs.(1a,b), (2a,b) and (3a,b). The MSD settles down to a constant value at long times, which persists even in the absence of a confining potential, whereas, $R(t)$ shows an exponential decay, starting from a finite value at $t=0$. These behaviours of the MSD and $R(t)$ are in sharp contrast to the case of a particle coupled to a bath via a position coupling [7] and the origin of these anomalous behaviours can be traced to the $\omega^3$ dependence of the force correlation functions as given in Eq.(5). Moreover, it can be surmised that the position response function in the case of a coupling via a momentum coordinate behaves as the velocity response function for the conventional case of a particle coupled to a bath via a position coordinate coupling, as position and momentum are conjugate variables connected by a derivative.

Furthermore, the formalism discussed here can be applied to other bath models and for generalized forms of couplings, for instance for a coupling strength varying as $\omega^4$ at low frequency for various values of $\delta$ and at all temperatures [4]. The change in the low frequency behaviours of the coupling strength is supposed to change the low frequency correlation function and the long time behaviours as we notice the anomalous behaviours of the
MSD and R(t), due to the $\omega^3$ dependence of the force correlation in the Fourier domain. This type of anomalous coupling can be realized practically, for example, when one considers the effect of black body electromagnetic field in Josephson junction [14, 25].

We expect the results of our study to induce the experimentalists to test them in a state of the art cold atom laboratory, along the lines of the experiments carried out for anomalous diffusion of cold atoms [26–29].

\[ C(t) = C_1(t) + C_2(t) \]  (48)

where,

\[ C_1(t) = (-2\pi i) \sum_{j=1}^{4} (\text{Res}[C(\omega)\exp(-i\omega t), p_j]) \]  (49)

\[ C_2(t) = (-i\hbar \Omega_{th}) \sum_{n=1}^{\infty} R^n(-in\pi \Omega_{th})\exp(-n\pi \Omega_{th}t) \]  (50)

\[ \text{Res}[C(\omega)\exp(-i\omega t), p_j] \text{ is the residue of } C(\omega)\exp(-i\omega t) \text{ corresponding to pole at } p_j \]

\[ I_1 = \text{Res}[C(\omega)\exp(-i\omega t), p_1] \]

\[ = \left[ e^{-i\text{t}^\left(-m(\omega_c + i\gamma) + \sqrt{4m^2\omega^2_0 + 2m(\omega_c + i\gamma)^2}\right)} \frac{2im^2{\omega}^2 + m \left( \sqrt{4m^2\omega^2_0 + 2m(\omega_c + i\gamma)^2} - m(\omega_c + i\gamma) \right) (-i\omega_c + \gamma) \left( \frac{\gamma m}{\pi \omega_0} \right) \hbar}{16mm^2\pi \gamma \sqrt{4m^2\omega^2_0 + 2m(\omega_c + i\gamma)^2}} \right] \times \]

\[ \coth \left( \frac{\sqrt{4m^2\omega^2_0 + 2m(\omega_c + i\gamma)^2}}{2m_r \Omega} \right) \]  (51)

\[ I_2 = \text{Res}[C(\omega)\exp(-i\omega t), p_2] \]

\[ = \left[ ie^{i\text{t}^\left(-m(\omega_c + i\gamma) + \sqrt{4m^2\omega^2_0 + 2m(\omega_c + i\gamma)^2}\right)} \frac{2m^2{\omega}^2 + m \left( \sqrt{4m^2\omega^2_0 + 2m(\omega_c + i\gamma)^2} + m(\omega_c + i\gamma) \right) (\omega_c + i\gamma) \left( \frac{\gamma m}{\pi \omega_0} \right) \hbar}{16mm^2\pi \gamma \sqrt{4m^2\omega^2_0 + 2m(\omega_c + i\gamma)^2}} \right] \times \]

\[ \coth \left( \frac{\sqrt{4m^2\omega^2_0 + 2m(\omega_c + i\gamma)^2} + m(\omega_c + i\gamma)}{2m_r \Omega} \right) \]  (52)

\[ I_3 = \text{Res}[C(\omega)\exp(-i\omega t), p_3] \]

\[ = \left[ e^{-i\text{t}^\left(m(\omega_c - i\gamma) + \sqrt{4m^2\omega^2_0 + 2m(\omega_c - i\gamma)^2}\right)} \frac{2m^2{\omega}^2 + m \left( \sqrt{4m^2\omega^2_0 + 2m(\omega_c - i\gamma)^2} + m(\omega_c - i\gamma) \right) (i\omega_c + \gamma) \left( \frac{\gamma m}{\pi \omega_0} \right) \hbar}{16mm^2\pi \gamma \sqrt{4m^2\omega^2_0 + 2m(\omega_c - i\gamma)^2}} \right] \times \]

\[ \coth \left( \frac{\sqrt{4m^2\omega^2_0 + 2m(\omega_c - i\gamma)^2} + m(\omega_c - i\gamma)}{2m_r \Omega} \right) \]  (53)
\[ I_4 = \text{Res}[C(\omega)\exp(-i\omega t), p_4] \]

\[ = \left[ e^{\alpha(m(\omega_c + \gamma) + \sqrt{m\omega_0^2 + m^2(\omega_c - i\gamma)^2})} \right. \]

\[ \times \left. \frac{2im\omega_0^2 + m(-\sqrt{4m^2\omega_0^2 + m^2(\omega_c - i\gamma)^2} + m(\omega_c - i\gamma)) (i\omega_c + \gamma) \left( \frac{2m_r}{\pi\omega_0} \right) \hbar}{16mm_r^2\pi\gamma \sqrt{4m^2\omega_0^2 + m^2(\omega_c - i\gamma)^2}} \right] \]

\[ \coth \left( \frac{\sqrt{4m^2\omega_0^2 + m^2(\omega_c - i\gamma)^2} + m(-\omega_c + i\gamma)}{2m_r\Omega} \right) \]

\[ (54) \]

Therefore, the position autocorrelation function is given by:

\[ C(t) = (-2\pi i)(I_1 + I_2 + I_3 + I_4) + (-i\hbar\Omega_{th}) \sum_{n=1}^{\infty} R^n(-i\hbar\Omega_{th}) \exp(-n\pi\Omega_{th}t) \]

\[ = (-2\pi i)(I_1 + I_2 + I_3 + I_4) + \frac{\hbar \pi^4 \Omega_{th}^4}{mm_r\omega_0^2} \frac{e^{\pi\Omega_{th}t}(1 + 4e^{\pi\Omega_{th}t} + e^{2\pi\Omega_{th}t})}{(e^{\pi\Omega_{th}t} - 1)^4} \]

\[ \times \frac{\hbar \pi^4 \Omega_{th}^4(2m_r^2\omega_0^2 - m^2(\gamma^2 - 3\omega_c^2))}{mm_r^2\omega_0^{10}} \]

\[ (55) \]
