Gravitational wave memory is studied in the context of a certain class of braneworld wormholes. Unlike other wormhole geometries, this novel class of wormholes do not require any exotic matter fields for its traversability. First, we study geodesics in this wormhole spacetime, in the presence of a gravitational wave pulse. The resulting evolution of the geodesic separation shows the presence of displacement and velocity memory effects. Motivated by the same, we study the memory effects at null infinity using the Bondi-Sachs formalism, adapted for braneworld wormhole. Our analysis provides a non-trivial change of the Bondi mass after the passage of a burst of gravitational radiation and hence manifests the memory effect at null infinity. In both of these exercises, the presence of extra dimension and the wormhole nature of the spacetime geometry gets imprinted in the memory effect. Since future gravitational wave detectors will be able to probe the memory effect, the present work provides another avenue to search for compact objects other than black holes.

I. INTRODUCTION

The direct detection of gravitational waves (GWs) from binary black hole and binary neutron star merger events \(^\cite{1, 2}\), as well as the observations of the shadow of supermassive compact central objects e.g., the M87\(^*\) and the SgrA\(^*\) \(^\cite{3, 9}\), are the two major observational breakthroughs in the field of gravitational physics within the last decade. Both of these observations depend crucially on the strong field behaviour of gravity and, in principle, can be used to test the robustness of General Relativity (GR) and also provide crucial pointers on the nature of the compact objects \(^\cite{10–18}\). Despite the fact that — so far GR has passed these strong field tests without any scar — from a purely theoretical perspective, the inability of GR to correctly reconcile singularities occurring at the end point of gravitational collapse, or, as the starting point of our modern hot big bang cosmology, posits a serious challenge to the theory itself. This important shortcoming of GR must make room for investigating alternative possibilities, vis-a-vis modified near-horizon geometries. Among the alternatives, one can either look for higher curvature/higher dimensional theories of gravity, possibly emerging from some quantum gravity scenarios, or, modifications of the black hole paradigm itself. Such non-black hole compact objects can arise from quantum gravity-motivated theories e.g., fuzzballs \(^\cite{19}\) or, compact objects made out of exotic matter fields, known as ECOs \(^\cite{20–24}\). Both of these non-black hole objects, behave as a black hole for solar system tests of gravity, but appears to have distinct phenomenology, in contrast to that of the black hole, when they are probed using the strong field tests of gravity, e.g., gravitational waves \(^\cite{25–36}\).

One of the oldest as well as interesting ECOs correspond to the wormholes, which are spacetimes joining two distinct universes by a throat \(^\cite{37–42}\). If one can travel from one universe to the other, it will be refereed to as a traversable wormhole and this, in general, requires exotic matter fields. However, there exist one class of wormholes, which do not require exotic matter for its existence, known as the braneworld wormholes \(^\cite{43}\). This has two advantages — (a) the presence of higher dimension is imprinted on this wormhole solution and hence can possibly be tested using gravitational waves or, black hole shadow measurements, (b) the wormhole does not require any exotic matter on the four-dimensional brane, the contributions from higher dimensions take care of the exotic nature to support traversability of the wormhole. Therefore, it is worthwhile to study various properties of this wormhole and hence look for its observational signatures. This is because, it will not only validate the existence of wormholes, but also of compact extra dimensions, thus providing a unified testing ground for non-black hole nature of compact objects, vis-a-vis of theories beyond GR. Several aspects of this braneworld wormhole, e.g., its stability under perturbations due to various fields, in particular the ringdown structure \(^\cite{44}\), as well as implications for black hole shadow measurements \(^\cite{45}\), have already been explored. Intriguingly, all of these explorations have provided quite promising results and in particular, demonstrates the existence of echoes in the gravitational wave signal. In this work, we wish to explore another direction, which has remained largely unexplored, but holds immense potential for future generations of gravitational wave detectors, namely the gravitational memory effect.
With the improvement in the detection prospects for the future ground based gravitational wave detectors and also the launch of the space based-detector LISA in the near future, may provide us an opportunity to observe gravitational wave memory effect \[46\]. The memory effect brings in both the strong-field, as well as non-linear aspects of general relativity, which is yet to be observed. It refers to the lasting change in the relative distance between test particles when a gravitational wave passes through the ambient spacetime \[47\], \[48\]. Being a subtle DC shift to the overall gravitational wave amplitude, it has remained undetected in the past observations taken by LIGO \[49\]. There have been proposals of stacking the known GW signals observed by LIGO-Virgo in order to detect this effect \[50\]. Initially studied in the context of hyperbolic scattering \[51\] and gravitational bremsstrahlung \[52\], the memory effect was also shown to be sourced by gravitational waves \[53\]. Recent works on memory effects involve, generalization to electrodynamics \[54\], \[55\] and Yang-Mills theories \[56\], \[57\], distinguishing modified theories of gravity from GR, e.g., scalar-tensor theories \[58\], \[61\] and Chern-Simons gravity \[62\]. Moreover, there have also been works generalizing memory effects to the symmetries associated with near horizon geometries for black holes \[63\], \[65\]. In this work, we wish to study the gravitational memory effect for braneworld wormholes, a class of ECOs, for the first time. Our aim, in the present context, is to infer the imprints of the non-black hole nature of this static wormhole spacetime and the presence of extra dimensions on the memory effect. We attempt this exercise of finding the memory effects in two distinct ways — (a) we perform a geodesic analysis (as worked out in \[47\], \[66\]) and comment on the presence of displacement and velocity memory effect in the background wormhole spacetime by introducing an additional gravitational wave perturbation, (b) we study memory effects at null infinity using the Bondi-Sachs formalism \[67\]. Since the braneworld scenario, applicable to the present context, very much resembles a scalar-tensor theory of gravity, we use the formalism given in \[59\], and show how the variation in the Bondi mass aspect, related to the memory effect, depend on the change in the wormhole parameters. Moreover, the present work is crucial from both the observational and theoretical perspectives. In the former side, one can possibly generalise the present calculation for astrophysically relevant cases of rotating wormholes or rotating ECOs, in general. For the latter, this work can be used as a prospect to investigate supertranslations and soft hair implants on the throat of a wormhole geometry (analogous study for black hole horizons can be found in \[65\] and Rindler horizons in \[69\]). These issues we wish to study in the future.

The organization of the paper is as follows: in Section II we briefly review the wormhole geometry in the context of braneworld scenario. Section III deals with the study of geodesics and subsequent analysis of displacement and velocity memory effects and finally in Section IV we will study the influence of a perturbing gravitational wave on the wormhole metric in the Bondi-Sachs gauge and the associated null memory effects. We conclude with a discussion on the results obtained and provide an outline of the future directions to pursue.

II. BRIEF REVIEW OF WORMHOLE GEOMETRY IN THE BRANEWORLD SCENARIO

In this section, we will briefly review the braneworld scenario, which is of interest for the purpose of this work. In this model, we have a five dimensional bulk, within which two four dimensional branes are embedded. The extra dimension is spacelike and is described by a coordinate \(y\). One of the brane is located at \(y = 0\), the Planck brane and the other brane is located at \(y = \ell\), the visible brane. The proper distance between the two branes is given by, in general, \(d(x) = e^{\phi(x)}\ell\), where the field \(\phi\) is referred to as the radion field. Since we are interested in the low energy effective gravitational field equations from the perspective of a four-dimensional observer, it is wise to project the five dimensional Einstein’s equations on the four dimensional brane. Further, expanding the same in the ratio of (bulk/brane) curvature length scale, we finally obtain the following gravitational field equations on the visible brane,

\[
G_{\mu\nu} = \frac{\kappa^2}{\ell}\phi T^V_{\mu\nu} + \frac{\kappa^2 (1 + \Phi)}{\ell} T^P_{\mu\nu} + \frac{1}{\Phi} \left( \nabla_\mu \nabla_\nu \Phi - g_{\mu\nu} \nabla^\alpha \nabla_\alpha \Phi \right) - \frac{3}{2\Phi (1 + \Phi)} \left( \nabla_\mu \phi \nabla_\nu \phi - \frac{1}{2} g_{\mu\nu} \nabla^\alpha \nabla_\alpha \Phi \right). \tag{1}
\]

Here \(g_{\mu\nu}\) is the visible brane metric, \(\nabla_\mu\) is the covariant derivative with respect to \(g_{\mu\nu}\) and \(\kappa^2\) is the five dimensional gravitational coupling constant. \(T^P_{\mu\nu}\) and \(T^V_{\mu\nu}\) are the energy momentum tensors on the Planck brane and the visible brane, respectively. In order to avoid non-locality in the theory, through the energy momentum tensor of the Planck brane, we will work with \(T^P_{\mu\nu} = 0\) i.e., there is no matter on the Planck brane. The scalar field \(\Phi\), appearing in Eq. (1) is defined as, \(\Phi \equiv \exp[2e^{\phi(x)}] - 1\), where \(\phi(x)\) is the radion field. The field \(\Phi\) satisfies the following field equation,

\[
\nabla^\alpha \nabla_\alpha \Phi = \frac{\kappa^2}{\ell} \frac{T^V}{2\omega + 3} - \frac{1}{2\omega + 3} \frac{d\omega}{d\Phi} \left( \nabla^\alpha \Phi \right) \left( \nabla_\alpha \Phi \right), \tag{2}
\]

where, \(T^V\) is the trace of the energy momentum tensor on the visible brane and the coupling function \(\omega(\Phi)\), is
defined as,
\[ \omega(\Phi) = -\frac{3\Phi}{2(1 + \Phi)} \].

The above set of equations for the metric functions, as well as for the scalar field \( \Phi \), can be solved assuming a static and spherically symmetric metric ansatz along with an anisotropic fluid source on the visible brane. This simplifies the problem of solving the field equations a lot and one arrives at a two-parameter family of solutions with \( R = 0 \), written in the Schwarzschild coordinates as

\[
d s^2 = -\left(\kappa + \lambda \sqrt{1 - \frac{2M}{r}}\right)^2 d t^2 + \left(1 - \frac{2M}{r}\right)^{-1} d r^2 + r^2 \left(d \theta^2 + \sin^2 \theta d \phi^2\right).
\]

(4)

Here \( \kappa \) and \( \lambda \) are two wormhole parameters, such that when \( \kappa = 0 \) and \( \lambda = 1 \), Eq. (4) reduces to the familiar Schwarzschild line element with a singularity at \( r = 0 \) and an event horizon at \( r = 2M \). However, computation of \( R_{\mu\nu}\lambda\mu\nu\sigma\delta \) for the above spacetime ensures that there are no curvature singularities and it is also evident from Eq. (4) that as long as \( \kappa \) and \( \lambda \) are non-zero and positive, \( \theta_0 \neq 0 \) for \( r \geq 2M \) i.e., there is no event horizon in this spacetime. Though, the surface \( r = 2M \) is not an event horizon, it is null (as \( g^{rr} \) vanishes there) and hence in the above solution as well \( r = 2M \) is a special surface, and

is referred to as the throat of the wormhole. Physically, the above solution depicts two separate universes connected together at the throat, located at \( r = 2M \), which is traversable. This provides a broad introduction to the wormhole geometry we will be working with and shall apply the results mentioned above to the computation of memory effect, to be discussed below.

III. MEMORY OF GEODESICS

Apart from spacetime boundaries, memory effects can also be studied in the interior regions of a spacetime \[71\]. For example, in recent past, Zhang et al. \[66, 72\] have studied the memory effect by investigating the evolution of geodesics in exact plane gravitational wave spacetimes. By choosing a Gaussian pulse for the polarization (radiative) term in the line element, they solved the geodesic equations numerically, and then, computed the change in the separation and velocity (known as the displacement and the velocity memory, respectively) due to the passage of the GW pulse. Lately, there has been work in the framework of alternative theories of gravity \[73, 74\] to look for similar signatures. In the present work, we will study the evolution of the geodesics in the wormhole background, in the presence of a sech-squared gravitational wave pulse \[75\] and study how the displacement and velocity memory effects depend on the wormhole nature of the background geometry. For this purpose, we write down the perturbed line element in the Bondi-Sachs coordinates as follows,

\[
d s^2 = -\left(\frac{\kappa}{\kappa + \lambda} + \frac{\lambda}{\lambda + \kappa} \sqrt{1 - \frac{2m}{r}}\right)^2 d u^2 - 2 \left(1 - \frac{2m}{r}\right)^{-1/2}\left(\frac{\kappa}{\kappa + \lambda} + \frac{\lambda}{\lambda + \kappa} \sqrt{1 - \frac{2m}{r}}\right) d u d r
+ \left[ r^2 + r H(u) \right] d \theta^2 + \left[ r^2 - r H(u) \right] \sin^2 \theta d \phi^2.
\]

(5)

The GW pulse profile described by \( H(u) \) is taken to be, \( H(u) = A \text{sech}^2(u - u_0) \), where \( A \) denotes the amplitude of the GW pulse and it is centered around \( u = u_0 \).

Since the above wormhole spacetime along with the GW pulse respects the spherical symmetry, we can choose the equatorial plane, located at \( \theta = (\pi/2) \), to be the plane on which all the geodesics are located. Therefore, on the equatorial plane, the geodesic equations for the \( u \) coordinate becomes,

\[
\ddot{u} - \frac{f'}{2g} \dot{u}^2 - \frac{H - 2r}{2g} \phi^2 = 0 \text{.}
\]

(6)

\[ ^1 \text{Such pulses have been used in various other contexts as well, see [75, 76].} \]

Along identical lines one can arrive at the geodesic equations for the other coordinates on the equatorial plane, in particular, the respective geodesic equations for the \( r \) and the \( \phi \) coordinates are given as,

\[
\ddot{r} + \frac{f}{2g} \dot{r}^2 + \frac{f'}{g} \dot{r} \dot{u} + \frac{g'}{g} \dot{r}^2 + \frac{fH - 2fr - rgH'}{2g^2} \phi^2 = 0 \text{,}
\]

(7)

\[
\ddot{\phi} - \frac{H'}{r - H} \dot{\phi} + \frac{2r - H}{r(r - H)} \dot{\phi} = 0 \text{.}
\]

(8)

As mentioned before, all the above equations are written on the \( \theta = \pi/2 \) plane and here ‘overdot’ denotes derivative with respect to the proper time \( \tau \) associated with the geodesics, while ‘prime’ denotes derivative with respect to the argument of the respective function. For example,
\[ H' \equiv (dH/du) \text{ and } f' = (df/dr) \]. For convenience, we have introduced the functions \( f(r) \) and \( g(r) \) in the above geodesic equations; these are effectively the \( g_{uu} \) and \( g_{ur} \) components of the metric tensor, having the following expressions,

\[
f(r) \equiv \left( \frac{\kappa}{\kappa + \lambda} + \frac{\lambda}{\lambda + \kappa} \sqrt{1 - \frac{2m}{r}} \right)^2, \tag{9}
\]

\[
g(r) \equiv \left( \frac{\kappa}{\kappa + \lambda} + \frac{\lambda}{\lambda + \kappa} \sqrt{1 - \frac{2m}{r}} \right) \left( 1 - \frac{2m}{r} \right)^{-1/2}. \tag{10}
\]

We have solved the three geodesic equations, presented in Eq. (6)–Eq. (8) numerically in the symbolic manipulation software Mathematica and have analysed the solutions extensively. In particular, we have started by considering two neighbouring geodesics in the wormhole background and then have studied the evolution of their coordinate separation in terms of the proper time \( \tau \), which is also an affine parameter, see Fig. 1. Further, we have depicted in Fig. 2 how the evolution of these coordinate separations have been affected because of the presence of the gravitational wave pulse and also by the presence of extra dimension through non-zero values of \( \kappa \). In particular, as Fig. 2 demonstrates, even after the GW pulse has passed, there is a residual effect which manifests as the gravitational wave memory, more specifically, as the displacement memory effect. It turns out that these geodesics also inhibit velocity memory effects, which can be seen from Fig. 3.

Let us discuss the above scenario in detail and consider the various boundary conditions imposed on them. First of all, in this work we have considered two neighbouring timelike geodesics, which in the background wormhole geometry would satisfy the following condition on the equatorial plane,

\[-f(r)u^2 - 2g(r)\dot{u}^2 + r^2\dot{\phi}^2 - rH(u)\dot{\phi}^2 = -1. \tag{11}\]

We choose the initial conditions as follows: both the geodesics are chosen to have an initial separation in the radial coordinate \( r \), as well as in the null coordinate \( u \), however they both start at the same azimuthal coordinate \( \phi \). These geodesics have fixed initial values of \( \dot{r} \) and \( \dot{u} \), while the value of \( \dot{\phi} \) will depend on the background geometry through Eq. (11). Then we define the following quantities \( \Delta u \) and \( \Delta r \), as follows,

\[ \Delta u = u(\text{Geodesic II}) - u(\text{Geodesic I}), \]

\[ \Delta r = r(\text{Geodesic II}) - r(\text{Geodesic I}), \]

where, \( u(\text{Geodesic I}) \) and \( r(\text{Geodesic I}) \) corresponds to the coordinates associated with the geodesic I and \( u(\text{Geodesic II}) \) and \( r(\text{Geodesic II}) \) are the coordinates associated with the geodesic II. All of these are obtained by solving the geodesic equations, using appropriate initial conditions, as discussed before. We choose our pulse profile such as \( A = 1 \) and \( u_0 = 5 \). The results arising out of the time evolution of \( \Delta u \) and \( \Delta r \) for different values of wormhole parameters \( \kappa \) and \( \lambda \) have been depicted through the figures [Fig. 1a]–[Fig. 1d]. We first consider the \( \kappa \) variation by keeping \( \lambda \) fixed and keeping \( |\kappa| > |\lambda| \) for the validity of the wormhole solution. We consider three cases corresponding to the following values of \( \kappa \) — i) \( \kappa = 2.0 \), ii) \( \kappa = 1.5 \) and iii) \( \kappa = 1.2 \) with a fixed value of \( \lambda = 1.0 \). It is clearly seen from these plots that \( \Delta u \) is increasing with the decreasing values of \( \kappa \) (Fig. 1a), however, \( \Delta r \) is decreasing with the decreasing values of \( \kappa \) (Fig. 1b), i.e., \( \Delta u \) and \( \Delta r \) have opposite behaviours with change of \( \kappa \). We then consider the variation of \( \lambda \) by keeping \( \kappa \) fixed. Here again we demonstrate three cases: i) \( \lambda = 1.0 \), ii) \( \lambda = 0.5 \) and iii) \( \lambda = 0.05 \) and for all these cases, \( \kappa = 2.0 \). Here, we find that with the decrease in the value of \( \lambda \), there is a increase in \( \Delta u \), see Fig. 1c, while exactly the opposite scenario can be observed for \( \Delta r \) (Fig. 1d). As evident from these figures, the change \( \Delta u \) is more pronounced as compared to \( \Delta r \). For clarity, in Fig. 1 the GW pulse is represented by the filled region. The pulse we have shown in the plot is not the exact profile of the GW, rather we have used a scaled-up version of the original profile. The affine parameter interval for which the GW pulse remained significant remains unaltered. We will now discuss the emergence of displacement and velocity memory effect in the wormhole geometry.

Existence of displacement memory effect is evident from Fig. 2, where we have shown that the differences \( \Delta u \) and \( \Delta r \) between two neighbouring timelike geodesics depends on whether a GW pulse has passed through them or, not. In other words, the values of \( \Delta u \) and \( \Delta r \) after the GW has passed through does not return to that of the wormhole background and hence provides the displacement memory effect. This memory effect not only depends on the strength of the GW pulse, but more so on the background spacetime geometry. Different choices for the parameters \( \kappa \) and \( \lambda \) will lead to different deviations and hence to different memories. In particular, the memory effect can be a potential candidate to test the existence of additional hairs in the background spacetime outside a compact object. In the present scenario, it corresponds to the fact that non-zero \( \kappa \) does affect the displacement memory in neighbouring geodesics.

Finally, in addition to the displacement memory effect, the GW pulse in the wormhole geometry also describes a velocity memory effect, as clear from Fig. 3. Both \( \Delta u \) and \( \Delta r \) are non-zero and differ from their background values in the presence of the GW pulse. This memory effect also depends on the choice of the wormhole hair \( \kappa \) and possibly a combined study of displacement and velocity memory effect will lead to an existential proof of non-zero values of \( \kappa \). Therefore, we can conclude that both displacement and velocity memory effects exist in the case of braneworld wormhole and depends crucially on the choices of \( \kappa \) and \( \lambda \). This provides another avenue to search for these non-black hole compact objects, which can also hint at the existence of an extra spatial
(a) Variation of the difference between null coordinate of the two timelike geodesics, denoted by $\Delta u$ with respect to the proper time $\tau$, for different values of the higher dimensional parameter $\kappa$ has been presented.

(b) Variation of the difference between the radial coordinates of the timelike geodesics, namely $\Delta r$ has been presented against the proper time $\tau$ for different values of the wormhole parameter $\kappa$.

(c) Variation of the difference in the null coordinate between geodesics, i.e., $\Delta u$ has been depicted against the proper time $\tau$, for different choices of the parameter $\lambda$, for a fixed $\kappa$.

(d) Variation $\Delta r$ of the difference in radial coordinates between the two geodesics have been plotted with the affine parameter $\tau$ for different values of $\lambda$ and a fixed $\kappa$.

FIG. 1: Variation of the difference of both the coordinates between the timelike geodesics, namely $\Delta u$ and $\Delta r$ has been plotted with the proper time for different choices of the wormhole parameters.

dimension.

IV. BONDI-SACHS FORMALISM AND MEMORY EFFECT FROM NULL INFINITY

Having discussed the displacement and the velocity memory effects from the geodesic analysis in the previous section, we now focus our attention in investigating the memory effect at null infinity [53]. Since the effective gravitational field equations on the brane, as presented in Eq. (1), is equivalent to the generalized Brans-Dicke theory (since the Brans-Dicke parameter $\omega$ is also a function of the radion field), we try to reformulate the Bondi-Sachs analysis of the memory effect as prescribed in [59, 60] appropriately. As in the previous section, here also we assume that the spacetime of interest corresponds to a background wormhole spacetime with a GW pulse passing through it and as a consequence modifying the Bondi mass aspect. In particular, we try to derive the functional form of the Bondi mass aspect in terms of the wormhole parameters, which in turn are related to the physics of the higher spacetime dimensions.

For this purpose, first of all we have to express the background wormhole geometry in the null coordinates and then shall have to express the same in the Bondi-Sachs form by an expansion in the inverse powers of the radial coordinate $r$. The wormhole geometry in the null coordinates can be expressed as,

$$ ds^2 = -f(r)du^2 - 2g(r)dudr + r^2\gamma_{AB}dx^Adx^B, \quad (12) $$

where, $\gamma_{AB}dx^Adx^B$ corresponds to the line element on
(a) Variation of the difference between null coordinate of the two timelike geodesics, denoted by $\Delta u$, has been presented against the proper time $\tau$, in the presence of and in the absence of the GW pulse.

(b) Variation of the difference between the radial coordinates of the timelike geodesics, namely $\Delta r$, has been depicted with the proper time $\tau$ in the presence as well as in the absence of the GW pulse.

FIG. 2: The variation of $\Delta u$ and $\Delta r$ with the proper time of the geodesics have been presented in the presence and in the absence of GW pulse. The plots explicitly demonstrates that both $\Delta u$ and $\Delta r$ encodes information about the passage of the GW pulse in the past, thus depicts the displacement memory effect.

(a) Variation of the difference between the velocity along null direction $u$ of the two timelike geodesics, have been presented against the proper time $\tau$, in the presence as well as in the absence of the GW pulse.

(b) Variation of the difference between the velocity along the radial direction $r$ of the timelike geodesics has been presented with the proper time $\tau$ with and without the GW pulse.

FIG. 3: We have explicitly depicted that the expressions for $\Delta u$ and $\Delta r$ deviate significantly in the presence of a GW pulse. This immediately suggests the existence of a velocity memory effect.

the two sphere. At future null infinity $\mathcal{I}^+$, the metric above needs to be expanded in the powers of $1/r$, in order to match the above metric with the Bondi-Sachs form, which yields the following line element, correct the inverse power of the radial coordinate $r$, such that,

$$ds^2 = -du^2 - 2udu + r^2 \gamma_{AB} dx^A dx^B + \frac{2m\lambda}{r(\kappa + \lambda)} du^2 - \frac{2mk}{r(\kappa + \lambda)} dudr + O(r^{-2}).$$

This provides the behaviour of the spacetime geometry at future null infinity, while the similar result for matter fields needs to be discussed. The matter fields consist of two parts, the standard brane matter and the radion field. The radial dependencies of the on-brane matter field can be found in [43] and it follows that at future null infinity $\mathcal{I}^+$, the matter components fall off faster than $1/r^2$ and hence need not be considered for the calculation. On the other hand, the fall off behaviour of the radion scalar field at future null infinity can be parametrized as: $\Phi_b = \Phi_{0(b)} + \Phi_{1(b)}/r + \Phi_{2(b)}/r^2 + \cdots$, where ‘b’ denotes that these are contribution from the background wormhole geometry. The term $\Phi_{0(b)}$, which is the leading order term in the asymptotic expansion of
the radial field, reads,

$$\Phi_{0(b)} = \left( \frac{C_1}{m\lambda} \log \frac{\kappa + \lambda}{\kappa - \lambda} + C_4 \right)^2 - 1 .$$  \hspace{1cm} (14)

In an identical manner, we obtain the coefficients of \((1/r)\) and \((1/r^2)\) terms, in the asymptotic expansion of the as,

$$\Phi_{1(b)} = -\frac{2C_1}{\kappa + \lambda} \left( \frac{C_1}{m\lambda} \log \frac{\kappa + \lambda}{\kappa - \lambda} + C_4 \right) ,$$  \hspace{1cm} (15)

$$\Phi_{2(b)} = \frac{C_1^2}{(\kappa + \lambda)^2} + \frac{2m\kappa C_1}{(\kappa + \lambda)^2} \left( \frac{C_1}{m\lambda} \log \frac{\kappa + \lambda}{\kappa - \lambda} + C_4 \right) ,$$  \hspace{1cm} (16)

$$ds^2 = -du^2 - 2dudr + \frac{2m\lambda}{r(\kappa + \lambda)} du^2 - \left( \frac{2m\kappa}{r(\kappa + \lambda)} + \frac{b(u, \theta)}{r} \right) dr + \frac{2m\mu(u, \theta)}{r^2} du^2 - 2r^2 U(u, r, \theta) du d\theta$$  \hspace{1cm} (17)

Here, \(h_{AB} = \gamma_{AB} + c_{AB} r^{-1} + \mathcal{O}(r^{-2})\) and the terms \(b(u, \theta), m_p(u, \theta), U(u, r, \theta)\) and \(c_{AB}\) arise due to the presence of the GW pulse and can be considered as perturbations over and above the braneworld wormhole metric. Moreover, for the above perturbed metric to be consistent with the gravitational field equations, the radion field should be perturbed as well and the resultant field becomes \(\Phi = \Phi_b + \Phi_p\), where \(\Phi_b\) denotes the background radion scalar field and \(\Phi_p\) denotes the perturbed scalar field due to the scalar part of the GW pulse. We assume that the leading order term in \(\Phi_p\) is \(\mathcal{O}(1/r)\), such that the Bondi determinant condition can be expressed as,

$$\det(h_{AB}) = \left( \Phi_{0(b)}/\Phi \right)^2 \sin^2 \theta .$$  \hspace{1cm} (18)

which yields,

$$c_{AB} = \dot{c}_{AB} - \gamma_{AB} (\Phi_1/\Phi_{0(b)}) .$$  \hspace{1cm} (19)

Here, \(\dot{c}_{AB}\) is the pure gravitational part and corresponds to the transverse and traceless degrees of freedom. Also, in the above expression, \(\Phi_1 = \Phi_{1(b)} + \Phi_{1(p)}\), is the coefficient of the \(\mathcal{O}(1/r)\) term in the asymptotic expansion of the radion field \(\Phi\). Since there is an additional GW pulse being considered here, it will be described by a tensorial News \(N_{AB}\) as well as a scalar News \(N\), which are given by,

$$-\partial_u \dot{c}_{AB} = N_{AB}$$  \hspace{1cm} (20)

$$N = N_1 \sech^2 u \left( -2 Y^{20} \right) \begin{pmatrix} 1 & 0 \\ 0 & -\sin^2 \theta \end{pmatrix}$$  \hspace{1cm} (21)

Note that the \(\sech^2 u\) behaviour is assumed in order to be consistent with the discussion in the previous section and \(N_{AB}\) embodies the gravitational degrees of freedom, while \(N\) encodes the scalar degree of freedom. The amplitudes \(N_1\) and \(N_2\) are such that the GW pulse can be considered as perturbations over the wormhole background. Now, the Bondi determinant condition, along with integration of the above relations over the null coordinate \(u\), yields the following change in the Bondi shear \(c_{AB}\) as,

$$\Delta c_{AB} = \Delta \dot{c}_{AB} - \gamma_{AB} \frac{\Delta \Phi_{1(p)}}{\Phi_{0(b)}}$$

$$= -N_1 \left( -2 Y^{20} \right) \begin{pmatrix} 1 & 0 \\ 0 & -\sin^2 \theta \end{pmatrix} \int_{-\infty}^{\infty} \sech^2 u \ du - \frac{N_2}{\Phi_{0(b)}} \left( -2 Y^{20} \right) \begin{pmatrix} 1 & 0 \\ 0 & \sin^2 \theta \end{pmatrix} \int_{-\infty}^{\infty} \sech^2 u \ du$$

$$= -2 \left( -2 Y^{20} \right) \begin{pmatrix} N_1 + \frac{N_2}{\Phi_{0(b)}} & 0 \\ 0 & \sin^2 \theta \left( -N_1 + \frac{N_2}{\Phi_{0(b)}} \right) \end{pmatrix}$$  \hspace{1cm} (22)
Here, the term \(-2Y^2\) is the spin-weighted harmonic \(-2Y^2 = (3/4)\sqrt{5/6\pi} \sin^2 \theta\). The above equation, namely \(\Phi_{(22)}\) shows that the change in the Bondi shear, represented by \(\Delta_{\kappa AB}\) is not traceless, with the trace being dependent on the presence of the scalar memory via \(\Phi_{0(b)}\). Therefore, the existence of a non-zero trace for the Bondi shear will signal the presence of an additional scalar degree of freedom in the system, possibly arising from extra dimensions. These effects are clearly depicted in Fig. 4, where the behaviour of the Bondi- Sachs form of the wormhole metric with a GW pulse, as presented in Eq. (17), from which we find the following expressions in Bondi-Sachs formalism follows a nested pattern.

\[ ds^2 = -\exp[\sigma(u, r, \theta)] du^2 - 2\exp[2\beta(u, r, \theta)] du dr - 2r^2 \exp[2\{\gamma(u, r, \theta) - \delta(u, r, \theta)\}] U_1(u, r, \theta) du d\theta + r^2 \exp[2\{\gamma(u, r, \theta) - \delta(u, r, \theta)\}] d\theta^2 + r^2 \exp[2\{-\gamma(u, r, \theta) - \delta(u, r, \theta)\}] d\phi^2 . \]

The metric functions \(\sigma, \beta, U_1, \gamma, \delta\), appearing in the above expression, are all expanded in the inverse powers of the radial coordinate \(r\) yielding,

\[
\sigma(u, r, \theta) = \frac{\sigma_1(u, \theta)}{r} + \frac{\sigma_2(u, \theta)}{r^2} + \mathcal{O}(r^{-3}) \quad (24)
\]

\[
\beta(u, r, \theta) = \frac{\beta_1(u, \theta)}{r} + \frac{\beta_2(u, \theta)}{r^2} + \mathcal{O}(r^{-3}) \quad (25)
\]

\[
U_1(u, r, \theta) = \frac{U_{11}(u, \theta)}{r} + \frac{U_{12}(u, \theta)}{r^2} + \mathcal{O}(r^{-3}) \quad (26)
\]

\[
\gamma(u, r, \theta) = \frac{\gamma_1(u, \theta)}{r} + \frac{\gamma_2(u, \theta)}{r^2} + \mathcal{O}(r^{-3}) \quad (27)
\]

\[
\delta(u, r, \theta) = \frac{\delta_1(u, \theta)}{r} + \frac{\delta_2(u, \theta)}{r^2} + \mathcal{O}(r^{-3}) \quad (28)
\]

These expansions must be compared with the Bondi-Sachs form of the wormhole metric with a GW pulse, as presented in Eq. (17), from which we find the following correspondence,

\[
\sigma_1(u, \theta) = -\frac{2m\lambda}{\kappa + \lambda} - 2m_p(u, \theta) , \quad \beta_1(u, \theta) = \frac{m\kappa}{\kappa + \lambda} + \frac{b(u, \theta)}{2} , \quad \delta_1(u, \theta) = \frac{\Phi_1}{2\Phi_{0(b)}} , \quad \gamma_1(u, \theta) = \frac{c_{\theta\theta}}{2} = \frac{\dot{c}(u, \theta)}{2} , \quad \delta_2(u, r, \theta) = U(u, r, \theta)
\]

\[
= \frac{\Phi_2 U_1(u, r, \theta)}{2\Phi_{0(b)}} \exp[2\{\gamma(u, r, \theta) - \delta(u, r, \theta)\}] . \quad (29)
\]

To proceed further, we use the fact that the field equations in Bondi-Sachs formalism follows a nested pattern. One starts with an initial data, prescribed in terms of the functions \(c_{\theta\theta}(u, \theta)\) and \(\Phi_{1(p)}(u, \theta)\) at some value of \(u\). Subsequently, the hypersurface equations \(G^u_r\) and \(G^u_\theta\), respectively yields,

\[
\mathcal{O}(r^{-1}) : \quad U_{11} = 0 , \quad \mathcal{O}(r^{-2}) : \quad U_{12}(u, \theta) = -\frac{\partial_r \hat{c}(u, \theta)}{2} - \hat{c}(u, \theta) \cot \theta , \quad (30)
\]

and finally, at order \(\mathcal{O}(r^{-3})\), we obtain,

\[
\beta_1 = -\frac{\Phi_1(u, \theta)}{2\Phi_{0(b)}} ; \quad b(u, \theta) = -\frac{\Phi_1(u, \theta)}{\Phi_{0(b)}} - \frac{2m\kappa}{\kappa + \lambda} . \quad (32)
\]

Similarly, the hypersurface equation in the \(G^u_u\) component of Einstein’s equations yields an identity at the lowest order of \(\mathcal{O}(r^{-2})\), while the supplementary equation for the component \(G^r_r\) at \(\mathcal{O}(r^{-2})\) yields the change in the Bondi mass aspect of the system,

\[
\sigma_{1, u} = \frac{(\partial_u \Phi_1)^2}{2\Phi_0} - \frac{3}{2} \frac{(\partial_u \Phi_1)^2}{2\Phi_0} - \frac{\Phi_1 \partial_r^2 \Phi_1}{\Phi_0^2} - \frac{\partial_u \Phi_1}{\Phi_0} + \frac{(\partial_u \dot{c})^2}{2} + \partial_u \dot{c} - \frac{3}{2} \partial_u \partial_\theta \dot{c} \cot \theta - \frac{1}{2} \partial_u \partial_\theta^2 \dot{c} . \quad (33)
\]

Integrating the above expression, we obtain the effective

\[2\text{Since the system is axisymmetric, the spherical harmonic is chosen in a way such that there is no dependence on } \phi. \]

\[3\text{The following field equations are solved using the RGTC package in the symbolic manipulation software Mathematica.}\]
We have depicted the variation of the Bondi shear with the wormhole hair $\kappa$ on the $\theta = (\pi/2)$ plane. The variation of the Bondi shear with the parameter $\lambda$ has been presented here on the equatorial plane. Variation of the Bondi shear due to the GW pulse has been presented against $\theta$ for different choices of the wormhole hair $\lambda$. Response of the change in Bondi shear due to the GW pulse has been presented against $\theta$ for different values of $\kappa$, but with a fixed choice for $\lambda$.

FIG. 4: Variation of Bondi shear due to the passage of a GW pulse, also known as the memory tensor has been presented for various choices of the wormhole parameters.

Bondi mass of the system to yield,

$$m_p = - \frac{m \lambda}{\kappa + \lambda} - \frac{1}{2} \left[ a^2 Y^2 - b^2 Y^2 \left\{ \frac{1}{2 \Phi_0^2} - \frac{3}{2 \Phi_0^2 (1 + \Phi_0)} \right\} \right]$$

$$\left( \frac{2}{3} \tanh u + \frac{1}{3} \text{sech}^2 u \tanh u \right)$$

$$- \frac{1}{3 \Phi_0^3} b^2 Y^2 \tanh^3 u$$

$$+ \frac{1}{2} \tanh u \left( \frac{b Y}{\Phi_0} + a Y + \frac{3}{2} a Y,_{\theta} \cot \theta + a Y,_{\phi} \right).$$

(34)

The evolution of the Bondi mass with variation in $\kappa$ and $\lambda$ has been depicted in Fig. 5. In the plot of Fig. 5a, we find that the change in Bondi mass is almost negligible around $\kappa = 10$, while for smaller and larger value of $\kappa$, we find a substantial change in the Bondi mass. On the other hand, in Fig. 5b, we find that the change in the Bondi mass is independent of the change in the value of $\lambda$. This is akin to the behaviour of the Bondi shear which also had a significant dependence on the choice of $\kappa$, rather than on $\lambda$.

V. CONCLUSIONS

In this article, we have explored certain aspects of the gravitational wave memory in a wormhole background on the brane. The reason for considering the presence of extra spacetime dimension is two-fold — i) The on-brane gravity theory is a quasi scalar-tensor theory, with the scalar field capturing the imprints of the spatial extra dimension and hence any information about the scalar hair will translate into possible inputs for the extra dimensions. ii) In this class the wormhole geometry is traversable and can be sustained without invoking any exotic matter fields. In this manner we arrive at a possible non-black hole compact object without using exotic...
variation of the change in the Bondi mass due to GW pulse has been presented with the null coordinate $u$, for different choices of $\kappa$, with $\lambda = 3$.

(b) Variation of the change of Bondi mass aspect due to the GW pulse against the null coordinate $u$ has been presented with different choices of $\lambda$, for $\kappa = 6$.

FIG. 5: The evolution of the change in Bondi mass aspect due to GW pulse has been presented for various choices of the hairs present in the background wormhole spacetime.

We, at first, have briefly reviewed the geometry of the wormhole spacetime and how the presence of extra dimension helps in constructing a traversable wormhole without any exotic matter. Then we have explored the displacement and velocity memory effects by analysing neighbouring geodesics in the wormhole background in the presence of a localised GW pulse. We have shown explicitly, how the geodesic separation evolves before and after the passage of the pulse. This explicitly establishes the existence of both displacement and velocity memory effect. In addition, these memory effects depend crucially on the hairs of this wormhole solution and hence differs from the corresponding memory effect in Schwarzschild spacetime. Therefore, memory effects are indeed future pointers towards exploring existence of non-black hole compact objects in our universe, which in this context can also be related to the existence of extra spatial dimensions.

Having observed that indeed memory effect exists and depends on the details of the wormhole geometry, we subsequently proceeded to study the memory effect using symmetries at null infinity using the Bondi-Sachs formalism. For this purpose, we have expressed the spacetime metric of the wormhole geometry using the Bondi coordinate system and have expanded the radion field in inverse powers of the radial coordinate $r$. Considering a GW perturbation in the system that satisfies the Bondi gauge conditions, we have computed the Bondi shear as well as the Bondi mass aspect and hence observed that these also give rise to the memory effect. Again, the memory depends on the wormhole parameters ($\kappa, \lambda$) through the leading order contribution from the radial field. In particular, we have demonstrated that upon variation in the value of wormhole hair $\kappa$, the Bondi shear changes more rapidly, as compared to its variation in $\lambda$, a distinctive feature of the braneworld wormhole.

The memory effect encoded in the Bondi mass aspect is computed by solving the gravitational field equations of the theory at orders of $O(1/r)$. Decomposing the field equations into Hypersurface and Supplementary equations, we have determined the change in the Bondi mass of the system analytically. We find that upon increase in the value of $\lambda$, the change in the Bondi mass is almost constant, while for $\kappa$, in general there is a much pronounced variation. This shows that it will be easier to decipher whether the central compact object has a non-zero value of $\kappa$, since presence of a non-zero $\kappa$ will modify the memory significantly. Therefore, as and when the memory effect can be detected in the future GW detectors, it will possibly tell us about the existence of non-black hole compact objects and one can independently verify if the braneworld wormhole is a viable scenario.

There are several possible future extensions of the present work, first of all a complete analysis of the Bondi-Sachs formalism without assuming axisymmetry will be an interesting and important extension. Moreover, studying memory effect for rotating wormholes and other rotating compact objects, which are more relevant astrophysically, will be another interesting avenue to explore. Finally, studying gravitational wave memory effects for other black hole mimicker spacetimes, e.g., fuzzballs will be of significant interest.
