A Concurrent Program Logic with a Future and History

ROLAND MEYER, TU Braunschweig, Germany
THOMAS WIES, New York University, USA
SEBASTIAN WOLFF, New York University, USA

Verifying fine-grained optimistic concurrent programs remains an open problem. Modern program logics provide abstraction mechanisms and compositional reasoning principles to deal with the inherent complexity. However, their use is mostly confined to pencil-and-paper or mechanized proofs. We devise a new separation logic geared towards the lacking automation. While local reasoning is known to be crucial for automation, we are the first to show how to retain this locality for (i) reasoning about inductive properties without the need for ghost code, and (ii) reasoning about computation histories in hindsight. We implemented our new logic in a tool and used it to automatically verify challenging concurrent search structures that require inductive properties and hindsight reasoning, such as the Harris set.

1 INTRODUCTION

Concurrency comes at a cost, at least, in terms of increased effort when verifying program correctness. There has been a proliferation of concurrent program logics that provide an arsenal of reasoning techniques to address this challenge [6, 17, 22, 27–29, 32, 37, 45, 46, 54, 58, 65]. In addition, a number of general approaches have been developed to help structure the high-level proof argument [23, 24, 39, 52, 59]. However, the use of these techniques has been mostly confined to manual proofs done on paper, or mechanized proofs constructed in interactive proof assistants. We distill from these works a concurrent separation logic suitable for automating the construction of local correctness proofs for highly concurrent data structures. We focus on concurrent search structures (sets and maps indexed by keys), but the developed techniques apply more broadly. Our guiding principle is to perform all inductive reasoning, both in time and space, in lock-step with the program execution. The reasoning about inductive properties of graph structures and computation histories is relegated to the meta-theory of the logic by choosing appropriate semantic models.

Running Example. We motivate our work using Harris’ non-blocking set data structure [30], which we will also use as a running example throughout the paper.

We assume a garbage-collected programming language, supporting (first-order) recursive functions, product types, and mutable heap-allocated structs. The language further provides a compare-and-set operation, \( \text{CAS}(x, f, o, n) \), that atomically sets field \( f \) of \( x \) to \( n \) and returns \( \text{true} \) if \( f \)’s current value is \( o \), or otherwise returns \( \text{false} \) leaving \( x.f \) unchanged.

Harris’ algorithm implements a set data structure that takes elements from a totally ordered type \( K \) of keys and provides operations for concurrently searching for, inserting, and deleting a given operation key \( k \). We focus on the search operation shown in Figure 1. The data structure is represented as a linked list consisting of nodes implemented by the struct type \( N \). Each node stores a key and a next pointer to the successor node in the list. A potential state of the data structure is illustrated in Figure 1. The algorithm maintains several important invariants. First, the list is strictly sorted by the keys in increasing order and has a sentinel head node, pointed to by the immutable shared pointer \( \text{head} \). The key of the head node is \(-\infty\). Likewise, there is a sentinel tail node with key \( \infty \). We assume \(-\infty < k < \infty \) for all operation keys \( k \). To allow concurrent insertions and deletions without lock-based synchronization, a node that is to be removed from the list is first marked to indicate that it has been logically deleted before it is physically unlinked. Node marking is implemented by bit-stealing on the next pointers. We abstract from the involved low-level bit-masking using the function \( \text{is\_marked} \). A call \( \text{is\_marked}(p) \) returns \( \text{true} \) iff the mark bit of pointer
The workhorse of the algorithm is the function `find`. It takes an operation `key k` and returns a pair of nodes `(l, r)` such that `l.key < k ≤ r.key`, and the following held true at a single point in time during `find`’s execution: `r` was unmarked and `l`’s direct successor, and `l` was reachable from head. All client-facing functions such as `search` then use `find`.

**Contributions.** Recall that in order to prove linearizability of a concurrent data structure, one has to show that each of the data structure’s operations takes effect instantaneously at some time point between its invocation and return, the *linearization point*, and behaves according to its sequential specification [35]. The Harris set exhibits two key challenges in automating linearizability proofs of non-blocking data structures that we aim to address in our work.

The first challenge is that linearization points may not be statically fixed, but instead depend on the interference of concurrent operations performed by other threads. We discuss this issue using `search`, whose sequential specification says that the return value is `true` iff `k` is present in the data structure. Consider a thread `T` that executes a call `search(7)`. Figure 1 shows a possible intermediate state of the list observed right after the successful execution of the CAS on Line 16 during `T`’s execution of `search`. This is also the linearization point of search for `T`: the key 7 is currently not present in the data structure and search will return `false` because the condition `r.key == 7` on Line 23 will evaluate to `false` regardless of what other threads do, such as inserting 7 before `search(7)` returns. However, in an alternative execution, a concurrently executing `find` may precede `T` in executing the CAS that sets `l.next` to `r` so that by the time `T` executes Line 16, the condition `ln == r` is true. In this situation, the operation linearized when the pointer `ln` was read (i.e., on Line 7 or 14). In general, the correct linearization point may only be known in hindsight [52] at a later point in the execution. As a consequence, the proof must track information about earlier states

```plaintext
struct N = { val key: K; var next: N }

val tail = new N { key = ∞; next = tail }
val head = new N { key = −∞; next = tail }

procedure traverse(k:K, l:N, ln:N, t:N): (N × N × N) {
    val tn = t.next
    val tmark = is_marked(tn)
    if (tmark) return traverse(k, l, ln, tn)
    else if (t.key < k) return traverse(k, t, ln, tn)
    else return (l, ln, t)
}

procedure find(k: K): N × N {
    val ln = head.next
    val l, ln, r := traverse(k, head, ln, ln)
    if ((ln == r || CAS(l.next, ln, r))
       && !is_marked(r.next)) return (l, r)
    else return find(k)
}

procedure search(k: K) : Bool {
    val _, r = find(k)
    return r.key == k
}
```
Our first contribution is a lightweight embedding of computation histories into separation logic [51] that supports local proofs using hindsight arguments, but without having to perform explicit induction over computation histories.

The second challenge is that the proof needs to reason about maintenance operations that are local but affect an unbounded heap region. The procedure traverse guarantees that all nodes between \( l \) and \( r \) are marked. The \texttt{CAS} on Line 16 then unlinks the segment of marked nodes between \( l \) and \( r \) from the structure making \( r \) the direct successor of \( l \). This step is depicted in Figure 1. The blue edge between \( l \) and \( ln \) refers to the pre state of the \texttt{CAS} and the red edge between \( l \) and \( r \) to the post state. A traditional automated analysis needs to infer the precise inductive shape invariant about the traversed region (e.g. a recursive predicate stating that it is a list segment of marked nodes). Then, at the point where the segment is unlinked, it has to infer that the global data structure invariant is maintained. This involves an inductive proof argument, and the analysis needs to rediscover how this induction relates to the invariant of the traversal.

Our second contribution is a mechanism for reasoning about such updates with non-local effects. The idea is to compose these updates out of \textit{ghost update chunks}. This is illustrated in Figure 1, where the effect of the \texttt{CAS} is composed out of simpler updates that move the edge from \( l \) towards \( r \) one node at a time (indicated by the dashed red edges). One only needs to reason about four nodes to prove that the edge can be moved forward by one node. We refer to a correctness statement of such a ghost update chunk as a \textit{future}. The crux is to construct these futures during the traversal of the marked segment, i.e., in lock-step with the program execution. This avoids the need for explicit inductive reasoning at the point where the \texttt{CAS} takes effect. When proving the future for unlinking a single traversed node \( t \), we directly apply interference-free facts learned during the traversal, e.g., that \( t \) must be marked and can therefore be unlinked. We call this mechanism accounting. The final future can then be invoked on Line 16 to prove the correctness of the \texttt{CAS}.

The focus of the paper is on the development of the new program logic rather than algorithmic details on efficient automatic proof search. However, we have implemented a prototype tool called \texttt{plankton} that uses the logic to automatically verify linearizability of highly concurrent search structures. The tool’s implementation follows a standard abstract interpretation approach [11]. We have successfully applied the tool to verify several fine-grained non-blocking and lock-based concurrent set implementations, including: Harris set [30], Michael set [49], Vechev and Yahav CAS set [66, Figure 2], ORVYY set [52], and the Lazy set [31]. All these benchmarks require hindsight reasoning. To our knowledge, \texttt{plankton} is the first tool that automates hindsight reasoning for such a variety of benchmarks. The Harris set additionally requires futures that are also automated in plankton. With this, \texttt{plankton} is the first tool that can automatically verify the Harris set algorithm.

2 OVERVIEW

We aim for a proof strategy that is compatible with local reasoning principles and agnostic to the detailed invariants of the specific data structure under consideration. In particular, we want to avoid proof arguments that devolve into explicit reasoning about heap reachability or other inductive heap properties, which tend to be difficult to automate.

Our strategy builds on the \textit{keyset framework} [40, 59] for designing and verifying concurrent search structures. In this framework, the data structure’s heap graph is abstracted by a mathematical graph \( (N, E) \) where each node \( x \in N \) is labeled by its local contents, a set of keys \( C(x) \). The abstract state of the data structure \( C(N) \) is then given by the union of all node-local contents. Moreover, each node \( x \) has an associated set of keys \( KS(x) \) called its \textit{keyset}. The keysets are defined inductively over the graph such that the following \textit{keyset invariants} are maintained: (1) the keysets in the execution history to enable reasoning about linearization points that already happened in the past.
of all nodes partition the set of all keys, and (2) for all nodes \( x \), \( C(x) \subseteq KS(x) \). For the Harris set, we define \( C(x) \triangleq mark(x) \? \phi : \{ key(y) \} \) and let \( KS(x) \) be the empty set if \( x \) is not reachable from head and otherwise the interval \((key(y), key(x))\) where \( y \) is the predecessor of \( x \) in the list (cf. Figure 2). Here, we denote by \( key(x) \) the value of field key in a given state, and similarly for \( mark(x) \). Throughout the rest of the paper, we will follow this convention of naming variables in a way that reflects the referencing mechanism.

The keyset invariants ensure that for any node \( x \in N \) and key \( k \)
\[
k \in KS(x) \Rightarrow (k \in C(N) \Leftrightarrow k \in C(x))
\]

This property allows us to reduce the correctness of an insertion, deletion, and search for \( k \) on the global abstract state \( C(N) \) to the correctness of the same operation on \( x \)'s local contents \( C(x) \), provided we can show \( k \in KS(x) \). For example, suppose that a concurrent invocation of \( \text{search}(k) \) returns \( \text{false} \). To prove that this invocation is linearizable, it suffices to show that there exists a node \( x \) such that both \( k \in KS(x) \) and \( k \notin C(x) \) were true at the same point in time during \( \text{search}(k) \)'s execution. We refer to \( x \) as the decisive node of the operation. The point in time where the two facts about \( x \) hold is the linearization point.

The ingredients for the linearizability proofs are thus (i) defining the keysets for the data structure at hand, (ii) proving that the keyset invariants are maintained by the data structure’s operations, and (iii) identifying the linearization point and decisive node \( x \) for an operation on key \( k \) by establishing the relevant facts about \( k \)'s membership in the keyset and contents of \( x \).

Our contributions focus on the automation of (ii) and (iii). While we do not automate (i), the definition of the keyset follows general principles and can be reused across many data structures [59] (e.g., we use the same definition for all the list-based set implementations considered in our evaluation, cf. §8). In the remainder of this section, we provide a high-level overview of the reasoning principles that underlie our new program logic and enable proof automation.

**Automating History Reasoning.** We start with the linearizability argument. Consider a concurrent execution of \( \text{search}(k) \) that returns value \( b \). The decisive node of \( \text{search} \) is always the node \( r \) returned by the call to \( \text{find} \). The proof thus needs to establish that at some point during the execution, \( k \in KS(r) \) and \( b \Leftrightarrow (k \in C(r)) \) were true. The issue is that when we reach the corresponding point in the execution during proof construction, we may not be able to linearize the operation right away because the decisive node and linearization point depend on the modifications that may still be done by other threads before \( \text{search} \) returns. We can thus only linearize the execution in hindsight, once all the relevant interferences have been observed.

To illustrate this point, consider the scenario depicted in Figure 2. It shows intermediate states of two executions of \( \text{search}(5) \) on a Harris set that initially contains the keys \{2, 5\}. The two executions agree up to the point when state \( s_1 \) is reached at the beginning of Line 7 in the first call to \( \text{traverse} \) (i.e., after \( n_2 \)'s next pointer and mark bit have been read). The execution depicted on the bottom proceeds without interference to state \( s_2 \) at the beginning of Line 17 and will return \( b = \text{true} \). Here, the decisive node is \( n_3 \) and the linearization point is \( s_1 \). Note that both \( 5 \in KS(n_3) \) and \( 5 \in C(n_3) \) hold in \( s_1 \). On the other hand, the execution depicted on the top of Fig. 2 is interleaved with a concurrently executing \( \text{delete}(5) \). The delete thread marks \( n_3 \) before the \( \text{search} \) thread reaches the beginning of Line 17, yielding state \( s'_2 \) at this point. The test whether \( r \) is marked will now fail, causing the \( \text{search} \) thread to restart. After traversing the list again, the \( \text{search} \) thread will unlink \( n_3 \) from the list with the \( \text{CAS} \) on Line 16. This yields state \( s'_1 \) when the \( \text{search} \) reaches Line 17 again. The \( \text{search} \) thread will then proceed to compute the return value \( b = \text{false} \). For this execution, the decisive node is \( n_4 \) and the linearization point is \( s'_2 \).

Our program logic provides two ingredients for dealing with the resulting complexity in the linearizability proof. We discuss these formally in §7. The first ingredient is the *past predicate* \( \Diamond p \),
discusses the definition of the predicate \( \{ -\infty \} \). We will use the following three rules in our proof:

\[ \text{H-INTRO} \quad \vdash \{ p \} \text{skip} \{ p \otimes p \} \]

\[ \text{H-HINDSIGHT} \quad p \text{ pure} \]

\[ \vdash p \otimes q \vdash (p \otimes q) \]

\[ \text{H-INFERENCE} \quad \vdash p \vdash q \]

\[ \otimes (\text{Node}(r) \ast k \in \text{KS}(r) \land (b \Leftrightarrow k \in \text{C}(r))) \]

as post condition where \( b \) is the return value of \( \text{search}(k) \). This implies the existence of a linearization point as discussed earlier. Here, we write \( 'e \) for the expression obtained from expression \( e \) by replacing all logical variables like \( \text{mark}(r) \) by fresh variables \( '\text{mark}(r) \). That is, \( 'e \) can be thought of as the expression \( e \) evaluated with respect to the old state of \( r \) captured by \( '\text{Node}(r) \) inside the past predicate, rather than the current state.

The symbolic execution starts from a global shared invariant that maintains \( \text{Node}(x) \) for all nodes \( x \in N \). When symbolic execution reaches Line 7 in the proof, we can establish shared ownership of \( \text{Node}(t) \) and \( \text{Node}(tn) \) using the derived invariant of the traversal. The two predicates imply that if \( t \) is unmarked, then its keyset must be non-empty. In turn, this implies \( \text{KS}(tn) = \)}
(key(t), key(\(tn\))], because \(tn\) is the successor of \(t\). Together, we deduce (a) \(\neg mark(t) \land key(t) < k \land k \leq key(\(tn\)) \Rightarrow k \in KS(\(tn\)). Moreover, the definition of \(C(\(tn\))\) gives us (b) \(k \in C(\(tn\)) \Leftrightarrow \neg mark(\(tn\)) \land key(\(tn\)) = k\). We let \(H(\(tn\), \(t\))\) be the conjunction of (a), (b), and Node(\(tn\)).

Next, we use rule \textsc{H Intro} to transfer \(H(\(tn\), \(t\))\) into a past predicate, yielding \(H(\(tn\), \(t\)) \circ \Diamond(H(\(tn\), \(t\))).\) For our proof to be valid, we need to make sure that all intermediate assertions are stable under interferences by other threads. Unfortunately, this is not the case for the assertion \(H(\(tn\), \(t\)) \circ \Diamond(H(\(tn\), \(t\))).\) Notably, this assertion implies that the current value of \(tn\)'s mark bit is the same as the value of its mark bit in the past state referred to by the past predicate.

To make the assertion stable under interference, we first introduce fresh logical variables 'key(\(tn\))' and 'mark(\(t\))' which we substitute for key(\(tn\)) and mark(\(tn\)) under the past operator. This yields the equivalent intermediate assertion:

\[
H(\(tn\), \(t\)) \circ \Diamond('H(\(tn\), \(t\))) \circ ('\text{mark(\(tn\))} = \text{mark(\(tn\))} \land 'key(\(tn\)) = \text{key(\(tn\))}).
\]

Next, we observe that other threads executing search, insert, and delete operations can only interfere by marking node \(tn\) in case it is not yet marked. Such interference invalidates the equality mark(\(tn\)) = 'mark(\(tn\)). So we weaken it to 'mark(\(tn\)) \Rightarrow mark(\(tn\)). In §4 we introduce a general Owicki-Gries-style separation logic framework that formalizes this form of interference reasoning. In addition, we keep only Node(\(tn\)) from \(H(\(tn\), \(t\)), leaving us with the interference-free assertion

\[
P(\(tn\), \(t\)) \equiv \text{Node(\(tn\))} \circ \Diamond('H(\(tn\), \(t\))) \circ ('\text{mark(\(tn\))} \Rightarrow \text{mark(\(tn\))}) \land 'key(\(tn\)) = \text{key(\(tn\))}.
\]

We then propagate this assertion forward along the considered execution path of search(\(k\)), obtaining \(P(\text{ln}, \(t\))\) when Line 17 is reached in the proof. During the propagation, we accumulate the facts \(\neg\text{mark}(\(t\)), \text{key}(\(t\)) < k, k \leq \text{key}(\(r\)),\) and \(\text{ln} = \text{r}\) according to the branches of the conditional expressions taken along the path. As these facts are all pure, we use rule \textsc{H Hindisight} to transfer them, together with the equality 'key(\(ln\)) = key(\(ln\)), inside the past predicate \(\Diamond('H(\text{ln}, \(t\))).\)

Using the rule \textsc{H Infer} we can then simplify the resulting past predicate as follows:

\[
\Diamond('\text{Node}(\(r\)) \equiv k \in 'KS(\(r\)) \land (k \in 'C(\(r\)) \Leftrightarrow \neg '\text{mark}(\(r\)) \land '\text{key}(\(r\)) = k)).
\]

As we propagate the overall assertion further to the return point of search(\(k\)), we accumulate the additional pure facts \(\neg\text{mark}(\(r\))\) and \(\text{b} \Leftrightarrow \text{key}(\(r\)) = k\). We again invoke rule \textsc{H Hindisight} to transfer these into the past predicate, together with 'mark(\(r\)) \Rightarrow mark(\(r\)) and 'key(\(r\)) = key(\(r\)). The resulting past predicate can then be simplified with \textsc{H Infer} to finally obtain the desired:

\[
\Diamond('\text{Node}(\(r\)) \equiv k \in 'KS(\(r\)) \land (b \Leftrightarrow k \in 'C(\(r\))).
\]

While this proof is non-trivial, it is easy to automate. The analysis performs symbolic execution of the code. After each atomic step, it applies the rules \textsc{H Intro} and \textsc{H Hindisight} eagerly. The resulting past predicates are then simplified and weakened with respect to interferences by other threads. This way, the analysis maintains the strongest interference-free information about the history of the computation. These steps are then integrated into a classical fixpoint computation to infer loop invariants, applying standard widening techniques to enforce convergence [12].

It is worth pointing out that the above reasoning could also be done with prophecies [38, 45]. However, prophecies are not amenable to automation in the same way as past predicates. The main reason for this is the hindisight rule: it works relative to facts that have already been discovered during symbolic execution. Prophecies would require to guess the same facts prior to being discovered. This guessing step is notoriously hard to automate [9].

**Automating Future Reasoning.** Our second major contribution is the idea of futures and their governing reasoning principles. We motivate futures with the problem of automatically proving that the Harris set maintains the keyset invariants. As noted earlier, this is challenging because the CAS performed by find may unlink unboudendly many marked nodes. Unlinking a node changes
We derive this future by composing two futures for simpler update chunks as depicted at the mark.

In particular the precondition $\text{CAS}(P)$ and postcondition $\text{CAS}(Q)$ of future $\mathcal{F}$ can be thought of as a Hoare triple with precondition $P$ and postcondition $Q$. However, futures inhabit the assertion level of the logic, rather than the meta level. The crux of our program logic is that it allows one to reuse the loop invariant for the proof of traverse towards proving the correctness of $\langle P \rangle \text{com} \langle Q \rangle$. This aids proof automation: the analysis no longer needs to synthesize the induction hypothesis out of thin air at the point where the CAS is executed. In a way, traverse moonlights as ghost code that aids the correctness proof of the CAS.

At the point where the CAS is executed, the proof then invokes the constructed future. A future can thus be thought of as a subproof that is saved up to be applied at some future point.

This idea is illustrated in Figure 3. The top left of the figure shows a state that is reached during the traversal of the marked segment from $l$ to $tn$. The transition at the top depicts the effect of the update $l.\text{next} := tn$ applied to this state. The update unlinks the marked nodes between $l$ and $tn$ in one step. The correctness of this update is expressed by the future

$$F \triangleq \langle P * \text{next}(l) = \text{ln} * \text{mark}(\text{ln}) \rangle \ l.\text{next} := tn \ \langle P * \text{next}(l) = tn \rangle$$

where $P$ is an appropriate invariant holding the relevant physical resources of the involved nodes. We derive this future by composing two futures for simpler update chunks as depicted at the bottom half of Figure 3. The left update chunk is described by the future

$$F_1 \triangleq \langle P * \text{next}(l) = \text{ln} * \text{mark}(\text{ln}) \rangle \ l.\text{next} := t \ \langle P * \text{next}(l) = t \rangle$$

and the right update chunk is described by

$$F_2 \triangleq \langle P * \text{next}(l) = t * \text{mark}(t) * \text{next}(t) = tn \rangle \ l.\text{next} := tn \ \langle P * \text{next}(l) = tn \rangle$$

$F_1$ is derived inductively during the traversal of the marked segment from $l$ to $t$ using the same process that we are about to describe for deriving $F$. The future $F_2$ can be easily proved in isolation. In particular the precondition $\text{mark}(t)$ implies $C(t) = \emptyset$. Hence, the keyset invariant $C(t) \subseteq \text{KS}(t)$

![Figure 3. A compound update (top) and its decomposition into update chunks (bottom). Compound updates may affect an unbounded number of nodes, e.g., changing their keysets. Update chunks allow to localize this effect of an update to a small, bounded number of nodes.](image)
is maintained. The condition \( \text{next}(t) = \text{tn} \) guarantees that the update does not affect keysets of other nodes beyond \( t \) and \( \text{tn} \).

We would now like to compose \( F_1 \) and \( F_2 \) using the standard sequential composition rule of Hoare logic to derive the future

\[
F' \triangleq \langle P \ast \text{next}(l) = \text{ln} \ast \text{mark}(\text{ln}) \rangle. \text{next} := t; l.\text{next} := \text{tn} \langle P \ast \text{next}(l) = \text{tn} \rangle.
\]

Once we have \( F' \), we get \( F \) by replacing the command \( l.\text{next} := t; l.\text{next} := \text{tn} \) in \( F' \) with \( l.\text{next} := \text{tn} \) using a simple subsumption argument.

However, sequential composition requires that the postcondition of \( F_1 \) implies the precondition of \( F_2 \). Unfortunately, the precondition of \( F_2 \) makes the additional assumptions \( \text{mark}(t) \) and \( \text{next}(t) = \text{tn} \) that are not guaranteed by \( F_1 \). Now, observe that both of these facts are readily available in the outer proof context of the traversal: \( \text{next}(t) = \text{tn} \) follows from Line 7 of \text{traverse} and \( \text{mark}(t) \) is obtained from the condition on Line 9. We can transfer these facts from the outer proof context into \( F_2 \). This eliminates them from the precondition and enables the sequential composition to obtain \( F' \). We refer to this transfer of facts as \textit{accounting}. In a concurrent setting, accounting is sound provided the accounted facts are interference-free. This is the case here since the \( \text{next} \) fields of marked nodes are never changed and marked nodes are never unmarked. We explain these reasoning steps in more detail in §6.

The idea of futures applies more broadly beyond this specific example. They are useful whenever complex updates are prepared in advance by a traversal phase (as e.g. in Bw trees [44] and skip lists [26]).

## 3 PROGRAMMING MODEL

We study concurrency libraries where an unbounded number of threads executes the same program code. Our development is parametric in the set of states and set of commands, following the approach of abstract separation logic [10, 19, 37].

**States.** We assume that states form a \textit{separation algebra}, a partial commutative monoid \((\Sigma, *, \text{emp})\). For the set of units \( \text{emp} \subseteq \Sigma \) we require that (i) for all \( s \in \Sigma \), there exists some \( 1_s \in \text{emp} \) with \( s * 1_s = s \) and (ii) for all distinct \( 1, 1' \in \text{emp} \), \( 1 * 1' \) is undefined. We use \( s_1 \# s_2 \) to indicate definedness.

**Predicates** are sets of states \( p \in \mathcal{P}(\Sigma) \). In the appendix, we introduce an assertion language to denote predicates but to simplify the exposition we stay on the semantic level. Predicates form a Boolean algebra \((\mathcal{P}(\Sigma), \cup, \cap, \subseteq, \emptyset, \Sigma)\). \textit{Separating conjunction} \( p \ast q \) lifts the composition from states to predicates. This yields a commutative monoid with unit \( \text{emp} \). \textit{Separating implication} \( p \rightarrow q \) gives residuals:

\[
p \ast q \triangleq \{ s_1 \ast s_2 \mid s_1 \in p \wedge s_2 \in q \wedge s_1 \neq s_2 \} \quad \text{and} \quad p \rightarrow q \triangleq \{ s \mid \{ s \} \ast p \subseteq q \}.
\]

In our development, \((\Sigma, *, \text{emp})\) is a product of two separation algebras \((\Sigma_G, \ast_G, \text{emp}_G)\) and \((\Sigma_L, \ast_L, \text{emp}_L)\). We require \( \text{emp} \triangleq \text{emp}_G \times \text{emp}_L \subseteq \Sigma \subseteq \Sigma_G \times \Sigma_L \). In addition, \( \Sigma \) must be closed under decomposition: if \((g_1 \ast_G g_2, l_1 \ast_L l_2) \in \Sigma \) then \((g_1, l_1) \in \Sigma \), for all \( g_1, g_2 \in \Sigma_G \) and \( l_1, l_2 \in \Sigma_L \).

For \((g, l) \in \Sigma \) we call \( g \) the \textit{global state} and think of it as the shared heap, although our development does not rely on this understanding. The component \( l \) is the \textit{local state}, and we think of it as a thread’s stack holding pointers through which to access the heap. States are composed component-wise, \((g_1, l_1) \ast (g_2, l_2) \triangleq (g_1 \ast_G g_2, l_1 \ast_L l_2) \), and this composition is defined only if the resulting product is again in \( \Sigma \).

**Lemma 1.** \((\Sigma, *, \text{emp})\) is a separation algebra.
A Hoare triple is valid if for every configuration 
while-language 
configuration 
The semantics of the library is defined in terms of unlabeled transitions among configurations.

A Concurrent Program Logic with a Future and History

Commands. The second parameter to our development is the set of commands \( \text{COM} \) that may be used to modify states. The set may be infinite, which allows us to treat atomic blocks as single commands. The effect of the commands on the states is defined by an interpretation. It assigns may be used to modify states. The set may be infinite, which allows us to treat atomic blocks as single commands. The effect of the commands on the states is defined by an interpretation. It assigns

\[
\text{new top element to the powerset lattice}
\]

reachable from \( cf \) and lift the notation to sets where needed.

Aborting commands return abort which is added as a new top element to the powerset lattice \( \mathbb{P}(\Sigma) \), so that \( \text{(LocCom)} \) is trivially satisfied.

Concurrency libraries. Having fixed the set of states and the set of commands, a concurrency library is defined by a single program that is executed in every thread. The assumption of a single program can be made without loss of generality. The program code is drawn from the standard while-language \( \text{ST} \) defined by:

\[
\text{st} ::= \text{com } | \text{st + st} | \text{st}; \text{st} | \text{st}^*.
\]

The semantics of the library is defined in terms of unlabeled transitions among configurations. A configuration is a pair \( \text{cf} = (g, \text{pc}) \) consisting of a global state \( g \in \Sigma_C \) and a program counter \( \text{pc} : \mathbb{N} \to \Sigma_L \times \text{ST} \). The program counter assigns to every thread, modeled as a natural number, the current local state and the statement to be executed next. We use \( \text{CF} \) to denote the set of all configurations. A configuration \( (g, \text{pc}) \) is initial for predicate \( p \) and library code \( \text{st} \), if the program counter of every thread yields a local state \( (l, \text{st}) \) where the code is the given one and the state satisfies \( (g, l) \in p \). The configuration is accepting for predicate \( q \), if every terminated thread \( (l, \text{skip}) \) satisfies the predicate, \( (g, l) \in q \).

We write these configuration predicates as the following sets

\[
\begin{align*}
\text{Init}_{p,\text{st}} & \triangleq \{(g, \text{pc}) | \forall i, l, \hat{\text{st}}. \text{pc}(i) = (l, \hat{\text{st}}) \Rightarrow (g, l) \in p \land \hat{\text{st}} = \text{st}\} \\
\text{Acc}_q & \triangleq \{(g, \text{pc}) | \forall i, l. \text{pc}(i) = (l, \text{skip}) \Rightarrow (g, l) \in q\}.
\end{align*}
\]

The unlabeled transition relation among configurations is defined in Figure 4. It relies on a labeled transition relation capturing the flow of control. A command may change the global state and the local state of the executing thread. It will not change the local state of other threads. A computation of the library is a finite sequence of consecutive transitions. A configuration is reachable if there is a computation that leads to it. We write \( \text{Reach(cf)} \) for the set of all configurations reachable from \( cf \) and lift the notation to sets where needed.

4 OWICKI-GRIES FOR CONCURRENCY LIBRARIES

We formulate the correctness of concurrency libraries as the validity of Hoare triples \( \{ p \} \text{st} \{ q \} \). A Hoare triple is valid if for every configuration \( cf \) that is initial wrt. \( p \) and \( \text{st} \), every reachable
configuration $cf'$ is accepting wrt. $q$. Note that the definition does not refer to a single but to all threads executing the library code.

**Definition 2.** $I\models \{p\} st \{q\} \triangleq \text{Reach}(\text{Init}_{p,\text{st}}) \subseteq \text{Acc}_q$.

To establish this validity, we develop a thread-modular reasoning principle [53] that proceeds in two steps. First, we verify the library code as if it were run by an isolated thread using judgments that take the form $P, I \vdash \{p\} st \{q\}$.

The Hoare triple of interest is augmented by two pieces of information. The set $P$ contains the intermediary predicates encountered during the proof of the isolated thread. The set $I$ contains the interferences, the changes the isolated thread may perform on the shared state. The notion of interference will be made precise in a moment. Recording both sets during the proof is an idea we have taken from [19, Section 7.3].

The second phase of the thread-modular reasoning is to check that the local proof still holds in the presence of other threads. This is the famous interference-freedom check. It takes as input the computed sets $P$ and $I$ and verifies that no interference can invalidate a predicate, denoted by $\equiv_T P$.

**Interference.** An interference is a pair $(o, \text{com})$ consisting of a predicate and a command. It represents the fact that from states in $o$ environment threads may execute command $\text{com}$. A state $(g, l)$ held by the isolated thread of interest will change under the interference to a state in $\llbracket (o, \text{com}) \rrbracket (g, l) \triangleq \{ (g', l) \mid \exists l_1, l_2. \ (g, l_1) \in o \land (g', l_2) \in \llbracket \\text{com} \rrbracket (g, l_1) \}$.

We consider every state $(g, l_1) \in o$ that agrees with $(g, l)$ on the global component, compute the post, and combine the resulting global component with the local component $l$. The agreement of different threads on the global state is precisely what is used in program logics like RGSep [61, 65]. We lift $\llbracket (o, \text{com}) \rrbracket$ to predicates in the expected way.

We only record interferences that have an effect on the global state. An interference $(o, \text{com})$ is **effective**, denoted by $\text{eff}(o, \text{com})$, if it changes the shared state of an element in $o$:

$$\text{eff}(o, \text{com}) \triangleq \exists (g_1, l_1). (g_1, l_1) \in o. \exists (g_2, l_2). (g_2, l_2) \in \llbracket \text{com} \rrbracket (g_1, l_1). g_2 \neq g_1.$$

The thread-local proof computes a set of interferences. For a predicate $o$ and a command $\text{com}$, the interference set is $\text{inter}(o, \text{com}) \triangleq \{ (o, \text{com}) \}$ if $\text{eff}(o, \text{com})$ and $\text{inter}(o, \text{com}) \triangleq \emptyset$ otherwise. We consider interference sets up to the operation of joining predicates for the same command, $\{(p, \text{com})\} \cup \{(q, \text{com})\} = \{(p \cup q, \text{com})\}$. Then $\text{inter}(o, \text{com}) \subseteq I$ means there is no interference to capture or there is an interference $(r, \text{com}) \in I$ with $o \subseteq r$. We write $I \ast r$ for the set of interferences $(o \ast r, \text{com})$ with $(o, \text{com}) \in I$. We also use the notation for sets of predicates $P$ and write $P \ast r$ for the set of predicates $p \ast r$ with $p \in P$.

The **interference-freedom check** takes as input a set of interferences $I$ and a set of predicates $P$. It checks that no interference can invalidate a predicate, $\llbracket (o, \text{com}) \rrbracket (p) \subseteq \text{Acc}_q$ for all $(o, \text{com}) \in I$ and all $p \in P$. If this is the case, we write $\equiv_T P$ and say the set of predicates $P$ is interference-free wrt. $I$.

The interference-freedom check is non-compositional, and in manual/mechanized program verification this has been the reason to prefer rely-guarantee methods [25, 61, 65]. From the point of view of automated verification, the difference does not matter. After all, there is no compositional way of computing the relies and guarantees.

**Program logic.** We define the derivation relation $\vdash$ inductively by the proof rules in Figure 5. $\text{COM-SEM}$ only adds the postcondition to the set of predicates to be checked for interference freedom. Similarly, the consequence rule $\text{INFER-SEM}$ neither adds the strengthened precondition nor the weakened postcondition. We can freely manipulate predicates as long as there is an interference-free predicate between every pair of consecutive statements, rule $\text{SEQ}$. To ensure this for loops
which may be left without execution, rule \textsc{loop} adds $p$ to the set of predicates. The initial predicate of the overall Hoare triple is added to the set of predicates by the assumption of Theorem 3 below.

As for the Hoare triples, the proof rules are standard except that they work on the semantic level. This is best seen in rule \textsc{com-sem}, which explicitly checks the postcondition for over-approximating the postimage.

\textbf{Theorem 3 (Soundness).} $P, I \vdash \{ p \} st \{ q \}$ and $\models_P$ and $p \in P$ imply $\models \{ p \} st \{ q \}$.

See Appendix E for the detailed proof of Theorem 3.

5 REASONING ABOUT KEYSETS USING FLOWS

Recall from \S 2 that we localize the reasoning about the abstract state $C(N)$ of the data structure to the contents $C(x)$ of a single node $x$ using its keyset $KS(x)$. In this section, we define the keysets as a derived quantity that we can reason about locally in a separation logic. Then, we use this formalism to define the node-local invariant $Node(x)$ of our running example. This node-level invariant is used by our tool to fully automatically generate a proof of the Harris list (cf. \S 8).

We derive the keyset of a node $x$ from another quantity $IS(x)$, the node’s \textit{inset}. Intuitively, $k \in IS(x)$ if a thread searching for $k$ will traverse node $x$. For the Harris set, we define $IS(head) = [-\infty, \infty]$ and for every other node we obtain $IS(x)$ as the solution of the following fixpoint equation:

$$IS(x) = \bigcup_{(y,x) \in E} IS(y) \cap (y.key, \infty].$$

Here, the set of edges $E$ is induced by the next pointers in the heap. If we remove those keys $k$ from $IS(x)$ for which a search leaves $x$ (i.e., if $k > x.key$ in the Harris set), we obtain $KS(x)$. These definitions ensure for free that the keysets are disjoint, the first of our keyset invariants. They also generalize to any search structure [59].

To express keysets in separation logic, we use the flow framework [41, 42]. In this framework, the heap is augmented by associating every node $x$ with a quantity \textit{flow}(x) that is defined as a solution to a fixpoint equation over the heap like that defining the inset above. Assertions describe disjoint fragments of the augmented global heap, similar to classical separation logic. The augmented heap fragments are called \textit{flow graphs}. In addition to tracking the flow of each node, a flow graph also has an associated interface consisting of an \textit{inflow} and an \textit{outflow}. The inflow \textit{in}(y, x) captures the contribution to the flow of $x$ inside the heap fragment via an edge from a heap node $y$ outside the fragment, and conversely for the outflow \textit{out}(x, y). Flow graphs $fg$ and $fg'$ compose if they are disjoint and their interfaces are compatible (i.e., the composed flow graph $fg * fg'$ has the same flow as the components). The framework then enables local reasoning about the effects of heap updates on flow graphs. In essence, if a local update inside a region $fg$ of a larger flow graph $fg$ * $fg'$
maintains \(fg\)'s interface, then the flow in \(fg\)' does not change. Hence, any property about \(fg\)' such as that each of its nodes \(x\) satisfies the keyset invariant \(C(x) \subseteq KS(x)\), can be framed across the update.

Appendix C provides the technical details of the flow framework adapted to the semantic setting of our program logic. For the remainder of the paper, it suffices to know that we instantiate the framework such that a node’s inset can be obtained from its flow as described above.

**The Harris’ set invariant.** We represent predicates \(p \subseteq \Sigma\) syntactically using separation logic assertions that are for the most part standard. In particular, we use boxed assertions \([A]\) that are inspired by RGSep [61, 65] to mean that \(A\) is interpreted in the global state. Unboxed assertions are interpreted in the local state. A points-to predicate takes the form \(x \mapsto (sel_i : t_i, \text{flow} : t_{\text{flow}}, \text{in} : t_{in})\) and describes a flow graph consisting of a single node \(x\). Here, each \(sel_i\) is a field selector and \(t_i\) is a term denoting the field’s associated value. The ghost field \(\text{flow}\) stores \(x\)'s flow and \(\text{in}\) stores its inflow. The semantics of assertions is defined by a satisfaction relation, which induces a denotation function \(\llbracket A \rrbracket \subseteq \Sigma\). We defer the technical details to Appendix D as they are standard.

We next define the resources associated with a node \(x\), its inset, and keyset. In proofs, we will assume that assertions are existentially closed, and will omit the corresponding outer quantifiers. Formulas like \(\text{Node}(x)\) defined in the following introduce logical variables like \(mark(x)\) that are visible beyond \(\text{Node}(x)\), for example, to define the keyset term \(KS(x)\). We define:

\[
\begin{align*}
\text{Node}(x) &\triangleq [x \mapsto \langle \text{mark} : mark(x), \text{next} : next(x), \text{key} : key(x), \text{flow} : \text{flow}(x), \text{in} : \text{in}(x) \rangle] \\
\text{IS}(x) &\triangleq x = \text{head} \iff [\infty, -\infty] : \text{flow}(x) \quad \text{KS}(x) \triangleq [\text{in}(x)] \setminus (\text{key}(x), \infty] .
\end{align*}
\]

With these definitions in place, we define the resource invariant \(\text{Inv}(N', N)\) that is maintained by each subregion \(N' \subseteq N\) of a Harris set structure consisting of nodes \(N\):

\[
\begin{align*}
\text{Inv}(N', N) &\triangleq \text{HD}(N) \otimes \star x \in N'. \text{Node}(x) \cdot \varphi^1(x) \cdot \varphi^2(x) \cdot \varphi^3(x, N) \cdot \varphi^4(x) \\
\text{HD}(N) &\triangleq \text{head} \in N \ast \text{key}(\text{head}) = -\infty \ast \neg \text{mark}(\text{head}) \\
\varphi^1(x) &\triangleq \neg \text{mark}(x) \Rightarrow \text{IS}(x) \neq \emptyset \\
\varphi^2(x) &\triangleq \text{IS}(x) \neq \emptyset \Rightarrow \{\text{key}(x), \infty\} \subseteq \text{IS}(x) \\
\varphi^3(x, N) &\triangleq \{x, \text{next}(x)\} \in N \wedge (\text{key}(x) = \infty \Rightarrow \neg \text{mark}(x)) \\
\varphi^4(x) &\triangleq \forall y, z. \text{in}(y)(y, x) \neq \emptyset \ast \text{in}(z)(x, x) \neq \emptyset \Rightarrow y = z
\end{align*}
\]

Formula \(\varphi^1(x)\) captures that all unmarked nodes are reachable from \(\text{head}\). Formula \(\varphi^2(x)\) implies the second keyset invariant \(C(x) \subseteq KS(x)\) and will also allow us to establish \(k \in KS(x)\) at the appropriate points in the proof. Formula \(\varphi^3(x)\) ensures \(N' \subseteq N\) and that \(N\) is closed under traversal of next pointers. It also implies that the tail node is unmarked. Finally, \(\varphi^4(x)\) implies that there exists at most one path from \(\text{head}\) to each \(x\) that a traversal would actually follow. This is needed to prove that unlinking marked nodes from the structure preserves the invariant. It is worth noting that the invariant does not put many constraints on the data structure shape. The sole purpose is to provide enough information to reason about the keysets.

If \(N\) is clear, we abbreviate \(\text{Inv}(N', N)\) to \(\text{Inv}(N')\). We will further freely use the following fact, which states that we can arbitrarily split and merge the invariant for disjoint subregions of the data structure for the purpose of framing.

**Lemma 4.** \(\text{Inv}(N_1 \cup N_2, N) \iff \text{Inv}(N_1, N) \ast \text{Inv}(N_2, N)\).
and then apply the developed principles to our concrete running example. The rule gives the implications we use for reasoning about futures. The rule comprises the entire marked footprint of Figure 6.

Reasoning about futures. Futures are expressed in terms of weakest preconditions. We define the weakest precondition, \( \wp(\text{com}, q) \), of a command \( \text{com} \) and predicate \( q \) in the expected way: \( \wp(\text{com}, q) \triangleq \{ s \in \Sigma \mid \llbracket \text{com}\rrbracket(s) \subseteq q \} \). The weakest precondition of the sequential composition \( \text{com}_1; \text{com}_2 \) is also defined as usual: \( \wp(\text{com}_1; \text{com}_2, q) \triangleq \wp(\text{com}_1, \wp(\text{com}_2, q)) \).

**Definition 5.** Futures are \( \langle p \rangle \text{com} \langle q \rangle \triangleq p \rightarrow \wp(\text{com}, q) \).

As futures are predicates, our assertion language treats futures as first-class assertions.

Readers familiar with Iris [37] will note that our definition of futures resembles Iris’ notion of Hoare triples. The key difference is that in Iris, the predicate \( p \rightarrow \wp(\text{com}, q) \) is additionally guarded by a persistence modality, making Hoare triples duplicable resources. That is, a Hoare triple in Iris can be used arbitrarily many times. In contrast, futures can carry resources and may therefore be subject to interference. Hence, they are not duplicable per se. This is a deliberate design choice motivated by the reasoning technique of accounting. We note that a future \( \langle p \rangle \text{com} \langle q \rangle \) is an ordinary duplicable Hoare triple if \( \text{emp} \subseteq \langle p \rangle \text{com} \langle q \rangle \).

Figure 6 gives the implications we use for reasoning about futures. The rule \textbf{F-INTRO} turns an ordinary Hoare triple that proves the correctness of a command \( \text{com} \) into a future. The rules \textbf{F-INFER} and \textbf{F-FRAME} correspond to the rules \textbf{INFER-SEM} and \textbf{FRAME} for Hoare triples. The rule \textbf{F-INVoke} allows us to invoke a future \( \langle p \rangle \text{com} \langle q \rangle \) at the point in the proof where the update chunk \( \text{com} \) is actually executed. That is, we can use this rule to discharge the premise of rule \textbf{COM-SEM}.

The composition of ghost update chunks is implemented by rule \textbf{F-SEQ}. It is similar to the rule for sequential composition in Hoare logic with two important differences. First, it requires a separating conjunction of the futures for the composed update chunks \( \text{com}_1 \) and \( \text{com}_2 \). The reason is that futures may carry resources. Second, it replaces the composition of \( \text{com}_1 \) and \( \text{com}_2 \) by a new update chunk.
con that is equivalent. Unlike the rule \textsc{seq}, the rule \textsc{f-seq} does not take into account interferences on the intermediate assertion \(p\). This is correct, since update chunks represent ghost computation that takes effect instantaneously, meaning \(\text{con}_1\) and \(\text{con}_2\) are executed uninterruptedly at the moment when the new update chunk \(\text{com}\) is invoked.

Finally, the rule \textsc{f-account} enables the partial invocation of a future \(\langle p \ast q \rangle \text{com} \langle o \rangle\) by eliminating the premise \(p\) if it is present in the current proof context. We refer to this rule as accounting. We have already seen in \S2 that accounting is useful to enable the composition of two futures using \textsc{f-seq}. Note that if \(p\) is subject to inference, so is the future \(\langle q \rangle \text{com} \langle o \rangle\) obtained from rule \textsc{f-account}.

The following lemma states the soundness of the rules.

\textbf{Lemma 6. The rules \textsc{f-intro}, \textsc{f-seq}, \textsc{f-infer}, \textsc{f-frame}, \textsc{f-account}, and \textsc{f-invoke} are valid implications.}

\textbf{Proving the Harris set invariant.} We demonstrate the versatility of futures by using them to prove that the CAS on Line 16 of the Harris set preserves the invariant of the data structure. Figure 7 shows the proof outline. The code is equivalent to the one in Figure 1, except that the mark bits have been made explicit. We discuss the key aspects of the proof in more detail.

The precondition of \text{traverse} contains the predicate \(T\text{Inv}(N, M, l, ln, lmark, t)\). It is the invariant of \text{traverse} and states that the data structure’s invariant \(\text{Inv}(N)\) is maintained. Additionally, the precondition contains the future \(\text{Fut}(M, l, ln, t)\). It captures the fact that the segment from \(l\) to \(t\) consisting of the nodes \(M\{l, t\}\) can be safely unlinked via the update \(l.next := t\), provided \(l.next = ln\) and \(\neg\text{mark}(l)\). After the update, the future guarantees that we have \((\text{key}(l), \infty) \subseteq \text{flow}(t)\), a crucial fact we will later use in the linearizability proof (cf. \S7).

To satisfy the precondition when invoking \text{traverse} from \text{find}, observe that the invocation is of the form \text{traverse}(k, head, hn, hn) where \(hn\) stems from \(hn = \text{head}.next\). The invariant \(T\text{Inv}(N, \{\text{head}, hn\}, \text{head}.next)\) follows from the data structure invariant \(\text{Inv}(N)\). The future \(\text{Fut}(\text{head}, hn, hn)\) can be obtained trivially via \textsc{f-intro} because the update \(\text{head}.next := hn\) has no effect if \(\text{next}(\text{head}) = hn\).

The postcondition of \text{traverse} contains the invariant \(T\text{Inv}(N, M, l, ln, lmark, r)\) and the future \(\text{Fut}(M, l, ln, r)\). By applying rule \textsc{f-invoke}, we can use the future to prove the correctness of the case where the CAS (\(l.next, ln, r\)) at Line 16 (Figure 1) succeeds. The remaining facts of the postcondition state that \text{traverse} has found the part of the data structure that contains the search key \(k\) if present.

The most interesting part of the proof is the transition between Lines 34 and 35, particularly the transition from \(\text{Fut}(M, l, ln, t)\) to \(\text{Fut}(M, l, ln, tn)\). Here, we need to extend the marked segment \(M\) by adding \(tn\). This step involves an application of \textsc{f-seq} to compose the update chunk for \(l.next := t\) with the one for \(l.next := tn\). We elaborate this step in detail, extending the discussion in \S2.

We start from \(\text{Fut}(M, l, ln, t)\) and use rule \textsc{f-frame} to extend both sides of this future with \(\text{Inv}(tn)\). The resulting future can be rewritten into the form

\[
\langle \hat{P}(l, t, tn, ln) * \text{Inv}(M \setminus \{l, t, tn\}) \rangle \quad l.next := t \langle \hat{Q}(l, t, tn, t) * \text{Inv}(M \setminus \{l, t, tn\}) \rangle
\]

where

\[
\hat{P}(l, t, tn, u) \triangleq \text{Inv}(\{l, t, tn\}) * next(l) = u * \neg\text{mark}(l)
\]

\[
\hat{Q}(l, t, tn, u) \triangleq \text{Inv}(\{l, t, tn\}) * next(l) = u * \neg\text{mark}(l) * (\text{key}(l), \infty) \subseteq \text{flow}(t).
\]

This future plays the role of \(\langle p \rangle \text{com}_1 \langle q \rangle\) in our application of rule \textsc{f-seq}. To obtain the future playing the role of \(\langle q \rangle \text{com}_2 \langle o \rangle\), we proceed in multiple steps. First, we use \textsc{f-intro} to derive

\[
\langle \hat{P}(l, t, tn, t) * next(t) = tn * \text{mark}(t) \rangle \quad l.next := tn \langle \hat{Q}(l, t, tn, tn) \rangle.
\]

To satisfy the premise of \textsc{f-intro}, we need to show that (i) the update \(l.next := tn\) is frame-preserving, i.e., the interface of the flow graph consisting of nodes \(\{l, t, tn\}\) does not change, and (ii) the invariants \(\varphi^t(x)\) are preserved for all \(x \in \{l, t, tn\}\). First observe that \(\neg\text{mark}(l)\) and \(\varphi^t(l)\)
We can now use \( \text{TInv} \) which follows from a concurrent program logic with a future and history. Applying \( \text{Fut} \) follows easily because \( \text{com} \) are unaffected by the update, so its invariant is trivially preserved. For \( t \), let \( \text{IS} = (\text{tn} \cap (\text{key}(l), \infty])) \). Observe that we have \( \text{IS}(\text{tn}) \subseteq \text{IS}'(\text{tn}) \neq \emptyset \), so the invariants for \( \text{tn} \) are also maintained. Finally, to show that the interface of the modified region remains the same, it suffices to prove \( \text{IS}(\text{tn}) \cap (\text{key}(l), \infty]) = \text{IS}'(\text{tn}) \cap (\text{key}(l), \infty]) \). This holds true if \( \text{key}(t) < \text{key}(\text{tn}) \), which follows from \( \varphi^3(t) \). The inset and inflow of \( l \) are unaffected by the update, so its invariant is trivially preserved. For \( t \), let \( \text{IS}'(t) = \emptyset \) denote the new inset. Since \( t \) is marked, this means that all its invariants are preserved. The new inset of \( \text{tn} \) is \( \text{IS}'(\text{tn}) = \text{IS}(\text{tn}) \cap (\text{key}(l), \infty]) \). The preparation guarantees that the \( \text{CAS} \) will maintain the invariant. We capture this with a future.

Next, we apply \( \text{F-ACCOUNT} \) for \( \text{tn} \) and use \( \text{F-FRAME} \) to add the remaining part \( \text{Inv}(M \setminus \{l, t, \text{tn}\}) \) of the segment \( M \) as a frame. This yields

\[
\langle \hat{P}(l, t, \text{tn}, t) * \text{Inv}(M \setminus \{l, t, \text{tn}\}) \rangle \text{l.next := } \text{tn} \langle \hat{Q}(l, t, \text{tn}, t) * \text{Inv}(M \setminus \{l, t, \text{tn}\}) \rangle.
\]

We can now use \( \text{F-SEQ} \) with this future and the one derived above. Note that the premise of the rule follows easily because \( \text{com}_1 \) and \( \text{com}_2 \) update the same memory location and \( \text{com} = \text{com}_2 \). We obtain

\[
\langle \hat{P}(l, t, \text{tn}, \text{ln}) * \text{Inv}(M \setminus \{l, t, \text{tn}\}) \rangle \text{l.next := } \text{tn} \langle \hat{Q}(l, t, \text{tn}, \text{tn}) * \text{Inv}(M \setminus \{l, t, \text{tn}\}) \rangle.
\]

Applying \( \text{F-INFER} \) and introducing a fresh existential \( M' \), we rewrite this into the form

\[
M' = M \cup \{l, t, \text{tn}\} \implies \langle \text{P}(M', l, \text{ln}, \text{ln}, \text{tn}) * \text{t} \in M' \rangle \text{l.next := } \text{tn} \langle \text{Q}(M', l, \text{ln}, \text{tn}, \text{tn}) \rangle.
\]

Now, we apply \( \text{F-ACCOUNT} \) one more time for \( t \in M' \) and use \( \text{tn} \in N, \text{ln} \in M, \text{l} \in M \subseteq N \) from the proof context, to obtain

\[
M' \subseteq N * \{l, \text{ln}, \text{tn}\} \subseteq M' * \text{Fut}(M', l, \text{ln}, \text{tn}).
\]

This allows us to reestablish \( \text{TInv}(N, M', l, \text{ln}, \text{ln}, \text{tn}) * \text{Fut}(M', l, \text{ln}, \text{tn}) \). As \( M' \) and \( M \) are existentially quantified, we can finally rename \( M' \) to \( M \), which yields the assertion on Line 35.
Checking interference freedom. We briefly discuss why the proof is interference free relative to other threads performing set operations. First, all commands maintain Inv(N) and N can only grow larger. Next, assertions depending on field key are interference free since a node’s key is never changed after initialization. Similarly, mark is only changed monotonically from false to true. Moreover, next is only changed for unmarked nodes (e.g., the proof guarantees ¬mark(I) in the successful case of the CAS on Line 16 and the insert operation provides a similar guarantee). This is why assertions such as mark(t) on Line 34 are interference free. Finally, futures constructed using rule F-INTRO are always interference free. All remaining futures are constructed by accounting interference-free facts or by composing interference-free futures via F-SEQ.

7 HISTORIES

We next present an extension of our developed theory that allows us to reason about separated computation histories. We integrate a form of hindsight reasoning for propagating knowledge between current and past states—hindsight is a key technique to handle non-fixed linearization points [23, 24, 43, 52]. We develop the new theory again in the general setting of §3 and §4 and then apply it to our running example.

History separation algebras. Recall that our states are taken from a separation algebra (Σ, ·, emp). We refer to a non-empty sequence of states, σ ∈ Σ+, as a computation history. Computation histories also form a separation algebra where composition on states is lifted to computation histories as follows. First, for sequences σ = s₁ . . . sₙ and τ = t₁ . . . tₘ, the composition σ · τ is defined, written σ # τ, if n = m and for all i, sᵢ # tᵢ. In this case, we let σ · τ = (s₁ · t₁) . . . (sₙ · tₙ). The set of units is given by emp⁺.

Lemma 7. (Σ⁺, ·, emp⁺) is a separation algebra.

Predicates a, b, c ⊆ Σ⁺ now refer to sets of computations. We lift the semantics of commands to computation predicates in the expected way.

Definition 8. \([[\text{com}}(σ.s₁)] \triangleq \{ σ.s₁.s₂ \mid s₂ ∈ [[\text{com}}(s₁) \}.

However, the locality assumption (LocCom) on the semantics of commands that is needed for the soundness of framing does not necessarily carry over from state predicates to computation predicates. If we want to frame computation predicates, we have to make an additional assumption.

Definition 9. A predicate a ⊆ Σ⁺ is frameable, if it satisfies ∀σ.∀s. σ.s ∈ a ⇒ σ.s.s ∈ a.

Lemma 10. If c is frameable, \([[\text{com}}(a \circ c)] \subseteq [[\text{com}}(a) \ast c.

We lift the semantics of concurrency libraries to history separation algebras (ΣG × ΣU)⁺. The notions of initial and accepting configurations, and soundness remain unchanged except that they now range over computation predicates instead of state predicates. The technical details of this lifting are straightforward, we defer them to Appendix G. The soundness guarantee in Theorem 3 continues to hold for history separation algebras modulo a subtlety. We can only apply rule FRAME if the predicate to be added is frameable in the sense of Definition 9.

Theorem 11 (Soundness). P, I ⊨ { a } st { b } and \(\equiv \) P and a ∈ P imply \(\models \{ a \} \text{ st } \{ b \}.

Frameable computation predicates. We next discuss general principles for constructing frameable computation predicates from state predicates.

Definition 12. State predicate p, q ⊆ Σ yield the following predicates over computations:
(i) The now predicate \(\neg p = Σ^+.p\).
(ii) The past predicate \(\neg p = Σ^+.p \ast Σ^+\).
The now predicate refers to the current state. The past predicate allows us to track auxiliary information about the computation. These predicates work well in our setting in that they are frameable.

**Lemma 13.** (i) \( _p \) and \( \otimes p \) are frameable. (ii) If \( a \) and \( b \) are frameable, so are \( a \ast b \), \( a \cap b \), and \( a \cup b \).

Frameability is not preserved under complementation and separating implication. However, the now operator is compatible with the SL operators in a strong sense.

**Lemma 14.** \( _p \otimes q = _p \otimes _q \) for all \( \otimes \in \{ \cap, \cup, *, \neg \} \). \( _p = _p \), \( \text{false} = _\text{false} \), \( \text{true} = _\text{true} \), and \( _p \subseteq _q \) iff \( p \subseteq q \).

For the past operator, we rely on the properties stated by the following lemma. In particular, the last equivalence justifies the rule \texttt{H-INFER} used in 2.

**Lemma 15.** \( _p \subseteq \otimes p \), \( \text{true} = \otimes \text{true} \), \( \text{true} \ast \otimes p = \otimes (p \ast \text{true}) \), \( \text{false} = \otimes \text{false} \), \( \otimes (p \ast q) \subseteq \otimes p \ast \otimes q \), \( \otimes (p \cap q) \subseteq \otimes p \cap \otimes q \), \( \otimes (p \cup q) = \otimes p \cup \otimes q \), and \( \otimes p \subseteq \otimes q \) iff \( p \subseteq q \).

The interplay between computation predicates and commands is stated in the following lemma. Recall that we defined \( \wp(\text{com}, a) \triangleq \{ \sigma \mid \llbracket \text{com} \rrbracket (\sigma) \subseteq a \} \).

**Lemma 16.** We have (i) \( \wp(\text{com}, _p) = _p \wp(\text{com}, p) \), and (ii) \( \wp(\text{com}, \otimes p) = \otimes p \cup \wp(\text{com}, _p) \).

The first identity of Lemma 16 implies that interference checking for a now predicate reduces to inference checking for the underlying state predicate. The second implies that past predicates are interference-free for all commands.

Next we justify the rule \texttt{H-INTRO} used in §2. Recall that this rule provides a way to record information about the current state in a past predicate so that we can use this information later in the proof. This involves a stuttering step.

**Lemma 17.** \( _p \subseteq \wp(\text{skip}, _p \ast \otimes p) \).

**Hindsight Reasoning.** We now use history separation algebras to justify the hindsight reasoning principle introduced in §2. The key idea is \textit{state-independent quantification}, and best explained with reference to an assertion language. An assertion language over computations will support quantified logical variables. As those quantifiers live on the level of computations, the resulting valuation of the logical variables will be independent of (the same for all) the states inside the computation. This means facts that we learn about the variables in one state will also be true in all other states. In particular, if we learn facts about a quantified variable now, we can draw conclusions in hindsight. We illustrate this on an example. In the assertion \( \exists v. (\otimes (x \mapsto v) \ast _{(v = 0)}) \), the logical variable \( v \) is quantified on the level of computations, meaning its value is independent of the actual state in the computation. We learn that now \( v \) is zero, and since the valuation is state independent, \( v \) has also been zero when \( x \) pointed to it. Hence, from the new state we can conclude, in hindsight, that also \( \otimes (x \mapsto 0) \) holds. This is indeed a consequence of the previous assertion (entailment holds). Rather than moving to an assertion language, we formalize this reasoning on the semantic level.

For hindsight reasoning, we construct a product separation algebra \( \Sigma^+ \times I \). The first component is the above history separation algebra \( (\Sigma^+, \ast, \text{emp}^+) \). We refer to the second component as \textit{valuation} or \textit{stack} separation algebra \( (I, \ast, I) \), because its elements can be understood as variable valuations. There are no requirements on \( I \), it is just an arbitrary set, but we note that it is also the set of units. The multiplication \( \ast \) between valuations \( i, j \in I \) is defined if and only if \( i = j \), in which case \( i \ast i = i \).

The product separation algebra \( \Sigma^+ \times I \) is the verbatim translation of the idea of state-independent quantification into the semantic world.
Predicates \( a \subseteq \Sigma^+ \times I \) over the product separation algebra are sets of pairs \((\sigma, i)\) consisting of a computation and a valuation. We lift the predicates \(^p\) and \(\Diamond p\) to \(\Sigma^+ \times I\) and let them refer to sets of the form \(^p\times J\) resp. \(\Diamond p\times J\) with \(J \subseteq I\). So, strictly speaking, the now and the past operator are relations rather than functions in this setting. Separation logic assertions are called pure, if they are independent of the heap and only refer to the valuation of logical variables. In the semantic setting, we define a predicate \(a\) to be pure, if it belongs to the set of units in the product separation algebra, \(a \subseteq \text{emp}^+ \times I\). The following lemma then justifies the rule \text{H-Hindsight} used in §2.

**Lemma 18.** If \(^p\) is pure, then \(^p\times q\) \(\subseteq \Diamond(p \times q)\).

**Proving linearizability of the Harris set.** By using the now predicate, we obtain a conservative extension of separation logic. In the following, the application of the now operator is kept implicit: a state predicate that occurs in a context expecting a computation predicate is interpreted as a now predicate. This is justified by Theorem 14.

We demonstrate the reasoning power of the resulting logic by proving linearizability of the search operation of the Harris set. The proof outline is in Figure 8, reusing our earlier proof of traverse. The code of \texttt{find} makes the semantics of the \texttt{CAS} explicit. We have also eliminated the case \(ln == r\) before the \texttt{CAS}. This focuses the discussion on a single linearization point. Appendix A gives the proof for the full version.

As in §2, we decorate logical variables occurring below a past operator with a prime to avoid clashes with variables describing the current state.

We proceed with the proof. First, observe the history assertion in the postcondition of \texttt{find}

\[
\Diamond (\texttt{Node}(r) \times (k \in \texttt{KS}(r))) \Rightarrow \neg \texttt{mark}(r) \times \texttt{key}(r) = \texttt{key}(r).
\]

Following our discussion from §2, the assertion \(\texttt{Node}(r) \times (k \in \texttt{KS}(r))\) below the past operator together with \(r \in N \Rightarrow \neg \texttt{mark}(r) \times \texttt{key}(r) = \texttt{key}(r)\) allows us to apply the keyset reasoning from §5: we obtain the predicate \(\Diamond\{k \in \texttt{C}(N) \iff k = \texttt{key}(r)\}\), Line 73. This means that \texttt{search} is linearizable.

To guarantee that the operation linearizes exactly once during its execution, we track an auxiliary ghost resource in the proof [61]. We write \(\text{Obl}(\text{search}(k))\) to denote the obligation to linearize operation \texttt{search} for key \(k\), Line 68. If a linearization point is found, we turn the obligation into a fulfillment \(\text{Ful}(\text{search}(k), b)\) where \(b\) is a Boolean indicating the expected return value. Here, we support hindsight reasoning as well: we let the above past predicate fulfill the obligation to linearize. More concretely, we use the following meta rules to discharge linearizability obligations for pure linearization points, i.e., those that do not modify the abstract state \(C(N)\):

\[
\text{Obl}(\text{search}(k)) \times \Diamond (k \in C(N)) \subseteq \text{Ful}(\text{search}(k), \text{true})
\]

and

\[
\text{Obl}(\text{search}(k)) \times \Diamond (k \notin C(N)) \subseteq \text{Ful}(\text{search}(k), \text{false})
\]

There are similar rules for the pure cases of insert and delete. For impure linearization points, obligations are turned into fulfillments in the current state, at the moment the linearization point occurs. We do not go into the details of these ghost resources, they are standard and orthogonal.

To prove the postcondition of \texttt{find}, we need to establish that at some point during the execution of \texttt{find}, \(k \in \texttt{KS}(r)\) and \(\neg \texttt{mark}(r)\) were satisfied. This is on Line 56, but we determine \(r\)‘s mark bit only later as execution continues past the condition on Line 62. The high-level proof idea is, thus, to record \(r\)‘s keyset and mark bit on Line 56 in the past assertion shown on Line 58 (we explain this step in more detail below). We then propagate the assertion on Line 58 into the then branch of the conditional (using Lemma 16). The logical variables link the past and current state, which allows us to apply hindsight reasoning (Rule \text{H-Hindsight}). Specifically, on Line 63 we know that \texttt{mark}(r) is false in the current state. Then, using \(\neg \texttt{mark}(r) \Rightarrow \texttt{mark}(r)\), we can conclude that \(\texttt{mark}(r)\) is
Fig. 8. Proof outline showing that Harris’ set search preserves the data structure invariant and is linearizable.
8 PROTOTYPE IMPLEMENTATION

We substantiate our claim that the presented techniques aid automation and are useful in practice. To that end, we implemented a C++ prototype called plankton. plankton takes as input the program under scrutiny and a candidate node invariant. It then fully automatically generates a proof within our novel program logic, establishing that the given program is linearizable and does adhere to the given invariant. We give a brief overview of plankton’s proof generation and report on our findings. We stress that the present paper focuses on the theoretical foundations and as such does not give a detailed discussion of plankton’s implementation.

Implementation. The proof generation in plankton is implemented as a fixpoint computation that saturates an increasing sequence \( I_0 \subseteq I_1 \subseteq \cdots \) of interference sets [33]. Initially, the interference set is empty, \( I_0 = \emptyset \). Once \( I_k \) is obtained, a proof of the input program with respect to \( I_k \) is constructed and the interferences \( I_{new} \) discovered during this proof are recorded, yielding \( I_{k+1} = I_k \cup I_{new} \). A fixpoint \( I_{fp} = I_k \) is reached if no new interference is found, \( I_k = I_{k+1} \). The proof generated for \( I_k \) is then the overall proof for the input program.

For the application of interferences during the proof to be efficient, it is crucial to reduce the size of the computed interference sets [64]. We reduce an interference set \( I \) by dropping any interference \( (o, com) \) from \( I \) that is already covered, that is, for which there is \( (r, com) \in I \) with \( o \subseteq r \).

Given an interference set \( I \), plankton constructs a proof \( I \vdash \{p_0\} \text{fun}\{q\} \) for each function \text{fun} of the input program. Proof construction starts from the precondition \( p_0 \), which captures just the invariant, as done, e.g., in Figure 8. From there, the rules of the program logic (Figure 5) are applied to inductively construct the postcondition. As \( I \) is fixed, plankton does not track the predicates \( \mathbb{P} \). We elaborate on the interesting ingredients of the proof construction.

Rule \text{com-sem} for atomic commands \text{com} requires plankton to compute \( \|\text{com}\|(p) \) for some precondition \( p \). The behavior of \( \|\text{com}\|(p) \) is prescribe by the standard axioms of separation logic [51]. If \text{com} updates the heap, however, we have to additionally infer a flow footprint such that, roughly (i) all nodes updated by \text{com} are contained in the footprint, (ii) the interface of the footprint remains unchanged by the update, and (iii) after the update all nodes inside the footprint still satisfy their node-local invariant. As discussed in §5, this localizes the update to the footprint: the nodes outside the footprint continue to satisfy the invariant. plankton chooses the footprint by collecting all nodes whose (non-flow) fields are updated by \text{com} and adds those nodes that are reachable in a small, constant number of steps. If this choice does not satisfy (i), verification fails. The restriction to finite footprints is essential for automating (ii) and (iii). Yet, the restriction does not limit our approach: unbounded footprints are handled with futures, as seen in §6. Conditions (ii) and (iii) are then encoded into SMT and discharged using Z3 [16]. Lastly, we apply the interferences \( I \) to \( \|\text{com}\|(p) \). The result is \( q \vdash \|I\|(\|\text{com}\|(p)) \) whose computation is inspired by [64]. Overall, we obtain \( I \vdash \{p\} \text{com}\{q\} \).

Rule \text{loop} requires a loop invariant \( I \) for program \( st^* \) and precondition \( p \) such that \( I \vdash \{I\} st \{I\} \) and \( p \subseteq I \). To find one, plankton generates a sequence \( I_0, I_1, \ldots \) of candidates. The first candidate is \( I_0 = p \). Candidate \( I_{n+1} \) is obtained from a sub-proof \( I \vdash \{I_n\} st \{I'_n\} \) whose pre- and postcondition are joined, i.e., \( I_{n+1} = I_n \cup I'_n \). Intuitively, this join corresponds to the disjunction \( I_n \cup I'_n \). For performance reasons, however, plankton uses a disjunction-free domain [55, 69], which means the join is actually weaker than union. A loop invariant \( I \vdash I_n \) is found, if the implication \( I_{n+1} \subseteq I_n \) holds.

A core aspect of our novel program logic are history and future predicates. plankton tries to construct a strongest proof for the input program. Hence, new history and future predicates are added eagerly to an assertion \( p \) whenever it participates in a join or interference is applied to it. The rational behind this strategy is to save information from \( p \) in a history/future before it is lost.
More specifically, all boxed points-to predicates from \( p \) that are subject to interference are added to a new history predicate. New futures are introduced either from scratch with rule \( \texttt{F-INTRO} \) followed by rule \( \texttt{F-ACCOUNT} \) or from existing futures with rules \( \texttt{F-SEQ} \) and \( \texttt{F-FRAME} \). It is worth pointing out that \( \texttt{plankton} \) uses rule \( \texttt{F-ACCOUNT} \) only to account duplicable facts, as in the proof from Figure 7.

The introduction of futures is guided by a set of candidates. These candidates are computed upfront by collecting all CAS commands in the input program. A CAS may be dropped from the candidates if its footprint is statically known to be finite, e.g., because it only updates the mark bit of a pointer or inserts a new (and thus owned) node. The approach discovers the necessary futures needed for our experiments. Avoiding unnecessary futures produced by this method is considered future work.

**Evaluation.** We used \( \texttt{plankton} \) to automatically verify linearizability of fine-grained state-of-the-art set implementations from the literature: a lock-coupling set [34, Chapter 9.5], the Lazy set [31], FEMRS tree [23] which is a variation of the contention-friendly binary tree [13, 14], Vechev&Yahav 2CAS set [66, Figures 8 and 9], Vechev&Yahav CAS set [66, Figure 2], ORVYY set [52], Michael set [49], Harris set [30], and a variation with wait-free search of the Michael and Harris set algorithms. For the FEMRS tree, \( \texttt{plankton} \) cannot handle the maintenance operations because they have updates with an unbounded footprint that is not traversed. This is a limitation of our current future reasoning. However, we are not aware of any other tool that can automatically verify even this simplified version of FEMRS trees. Also, \( \texttt{plankton} \) is the first tool to automate hindsight reasoning for the Harris set.

The results are summarized in Table 1. The first three columns of the table list (i) the number of iterations until the fixpoint \( \mathcal{I}_{\text{fix}} \) is reached, (ii) the size of \( \mathcal{I}_{\text{fix}} \), and (iii) the number of future candidates. The next five columns list the percentage of runtime spent on (iv) rule \( \texttt{COM-SEM} \), (v) future reasoning, (vi) history reasoning, (vii) joins, and (viii) applying interferences. The last column gives (ix) the overall runtime, averaged across 10 runs, and the linearizability verdict (success is marked with \( \checkmark \)). Across all benchmarks we observe that two iterations are sufficient to reach the fixpoint \( \mathcal{I}_{\text{fix}} \): the first iteration discovers all interferences, the second iteration confirms that none are missing. This is remarkable because the first iteration uses \( \mathcal{I}_0 \triangleq \emptyset \), i.e., considers the sequential setting. Further, we observe that most benchmarks spend significantly more time reasoning about the past than the future. The reason is twofold. (1) Introducing new futures either succeeds, meaning that a future candidate is resolved and can be ignored going forward, or it fails fast, which we attribute to Z3 finding counterexamples much faster than proving the validity of our SMT encoding of heap updates. (2) For histories, we do not have a heuristic identifying candidates. Instead, we eagerly introduce histories upon interference. We also apply hindsight reasoning eagerly. Lastly, we observe that the overall runtime tends to increase with the nesting depth and complexity of loops, as \( \texttt{plankton} \) requires several loop iterations (oftentimes between 3 and 5) to find an invariant. A proper investigation of how finding loop invariants affects the overall runtime is future work.

We also stress-tested \( \texttt{plankton} \) with faulty variations of the benchmarks. All buggy benchmarks failed verification. Note that \( \texttt{plankton} \) does not implement error explanation techniques, which are beyond the scope of the present paper.

### 9 RELATED WORK

**Program logics with history and prophecy.** Program logics have been extended by mechanisms for temporal reasoning in various ways [1, 6, 17, 27, 28, 32, 45, 46, 54, 56, 58].

The work closest to ours is HLRG [27], a separation logic based on local rely-guarantee [25] that tracks and reasons about history information, and its variation [28]. The separation algebra behind HLRG is constructed like ours. The focus of [27, 28], however, are temporal operators in
Table 1. Experimental results for verifying set implementations with plankton. The experiments were conducted on an Apple M1 Pro with 16GB of RAM running Ubuntu 20.10 with clang 12 and Z3 4.8.15.

</table>

the assertion language and means of reasoning about them in the program logic. We only have now and past, but add the ability to propagate information between them. The simplicity of our approach enables automation ([27, 28] is not even mechanized, as far as we know). A minor difference is that we work over general separation algebras to integrate flows [41, 42] easily and make the requirement of frameability explicit.

A program logic with temporal information based on different principles appears in [17, 58]. There, histories are sub-computations represented by timestamped sets of events. The product of histories is disjoint union. While highly expressive, we are not aware of implementations of the approach. Since our goal is automated proof construction, we strive for assertions that are simple to prove, instead.

A separation logic for proving producer-consumer applications is proposed in [6]. The logic uses history but is domain-specific and provides no mechanism to reason about the temporal development. A non-blocking stack with memory reclamation is verified in [54]. The proof relies on history information stored in auxiliary variables and manipulated by ghost code. The ghost code is justified by informal arguments (outside the program logic). We do not consider memory reclamation as it can be verified separately [47, 48]. Beyond linearizability, history variables have recently been used to give specs to non-linearizable objects [32].

Several separation logics have been extended with prophecy variables [38, 45], which complement history-based reasoning with a mechanism to speculate about future events. However, prophecies are not well-suited for automatic proofs because they rely on backward reasoning [9].

History reasoning has been used early on in program verification [1]. In program logics [46, 56], the focus has been on causality formulas which, in our notation, take the form \( p \Rightarrow \diamond q \). Our history reasoning is more flexible, in particular incorporates hindsight reasoning (see below), and inherits the benefits of modern separation logics.

Overall, existing program logics with history are heavier than ours while missing the important trick of communicating information from the current state to the past by means of logical variables shared between the two.

**Hindsight reasoning.** The idea of propagating information from the current state into the past is inspired by the recent hindsight theory [23, 24, 43, 52]. Hindsight lemmas ensure that information about a data structure obtained by sequential reasoning (typically the reachability of keys) remains valid for concurrent executions. The argument behind such results is that the existence of
a sequentially-reachable state implies the existence of a related concurrently-reachable state in the past. The implication requires that updates to the structure do not interfere with the reachability condition one tries to establish (forepassing condition in [24]).

So far, hindsight reasoning has been limited to pencil-and-paper proofs, with the exception of the poling tool [70]. poling automates the specific hindsight lemma of O’Hearn et al. [52]. Unlike histories, it does not immediately generalize to other forms of retrospective reasoning, like [23, 24, 43].

Our program logic makes past states explicit and can be understood as a formal framework in which to execute hindsight reasoning. The sequential-to-concurrent lifting of hindsight matches the thread-modular nature of our logic. This brings several benefits. For our engine, hindsight arguments provide a strategy for finding history information. For hindsight theory, it would be interesting to execute their arguments in our framework. This not only gives the classical benefits of program logics like precision and mechanization resp. automation. One also inherits the other features of our logic. We found futures indispensable to prove the Harris set.

**Futures.** Our futures are nothing but Hoare triples in separation logic (with separating implication), and their use as assertions is well-known from program logics like Iris [37]. What we add is the observation that futures capture complex heap updates by iteratively combining futures of small updates found during the traversal preparing the complex update. This iterative combination is the key novelty of our development. It allows us to reason about updates of unbounded heap regions by means of updates of finite regions.

Futures are inspired by atomic triples in TADA [15] and its predecessor CAP [21]. Atomic triples are specifications that justify an abstract notion of atomicity in a way that makes them suitable for constructing nested modules based on local specifications. Futures, although composed during the traversal, are also executed atomically upon the CAS. The difference is that an atomic triple is static in that the specification of the module is not meant to change during the execution. A future is instead built up during a loop that prepares the preceding update specified by the future.

On the more technical side, we note that futures carry resources whereas the nested Hoare triples in Iris are persistent [37]. The point is that our logic is not higher-order nor supports function pointers/recursion through the heap, therefore does not need step-indexed semantics [4] nor has to be careful about operators [57].

A method for automatically handling updates affecting unbounded heap regions is proposed in [60], however, their method is tailored towards reachability. Being Hoare triples, our futures are not restricted to a specific class of properties.

**Automation.** There is a considerable body of work on the automated verification of concurrent data structures. For static linearization points, there are tools [2] and well-chosen abstract domains [3]. For dynamic linearization points, there are reductions to safety verification [7–9]. Common to these works is that, in the end, they rely on a state-space search whereas our approach reasons in a program logic. Notably, the poling tool [70] extends cave [62–64] to support dynamic linearization points, e.g., to verify intricate stacks and queues (which we do not support because they are no search structures). Related is also [36] in the sense that flows in particular can express heap paths. But we are not interested in verification condition generation and complete reductions to SMT, but rather proof generation, including invariant synthesis.

Other promising tools automating program logics include Starling [67], Caper [20], Voila [68], and Diaframe [50]. However, these are closer to proof-outline checkers when compared to our tool. In particular, they do not perform loop invariant and interference inference or try to identify linearization points. Instead, they target more complex logics that are not designed for ease of automation.

B ADDITIONAL MATERIAL FOR SECTION 3

Example 19. We use a standard heap semantics of separation logic as a running example throughout this section. We consider heaps consisting of objects mapping fields to values. Let $Sel$ be a set of field selectors. Let further $Val$ be a set of values, $Addr \subseteq Val$ an infinite set of addresses, and $Var$ a set of program variables. A stack $i \in \Sigma_S \doteq Var \rightarrow Val$ is an assignment from program variables to values. A heap graph is a tuple $h = (X, sval)$ consisting of a finite set of nodes $X \subseteq Addr$ and a total valuation of the selectors $sval : X \times Sel \rightarrow Val$. Note that selectors may evaluate to nodes outside the heap graph. Let $HG$ be the set of all heap graphs.

The composition of heap graphs is the disjoint union, $h_1 *_H h_2 \doteq (h_1.X \uplus h_2.X, h_1.sval \uplus h_2.sval)$, and the empty heap is the only unit, $\bot \doteq (\emptyset, \emptyset)$. We extend the composition to pairs of stack and heap by defining $(i_1, h_1) *_{SH} (i_2, h_2) \doteq (i_1, h_1 *_H h_2)$ if $i_1 = i_2$. We then define the global states as $(\Sigma_G, *_G, emp_G) \doteq (\Sigma_H, *_H, emp_H)$ and the local states as $(\Sigma_L, *_L, emp_L) \doteq (\Sigma_S \times \Sigma_H, *_{SH}, \Sigma_S \times emp_H)$. A state is a pair of global and local state whose heaps are disjoint, $\Sigma \doteq \{ (h_G, (i_L, h_L)) \mid h_G \neq h_L \}$.

Example 20. Continuing with Example 19, we define the semantics of a field update command $l.next \doteq r$ that assigns the field $next$ of the object at address $l$ to value $r$ as follows:

\[
[l.next \doteq r] (h_G, (i, h_L)) = \begin{cases} 
\{ (h_G, (i, h_L)[:, (i(l), next) \mapsto i(r))] ) \} & \text{if } i(l) \in h_G.X \\
\{ (h_G[:, (i(l), next) \mapsto i(r)]), (i, h_L) ) \} & \text{if } i(l) \in h_G.C \\
\text{abort} & \text{otherwise.}
\end{cases}
\]

We lift $[l.next \doteq r]$ to predicates in the expected way and also define $[l.next := r](\text{abort}) = \text{abort}$.

Proof of Lemma 1. Assume that $(\Sigma_G, *_G, emp_G)$ and $(\Sigma_L, *_L, emp_L)$ are separation algebras and assume that $\Sigma$ is such that $emp_G \times emp_L \subseteq \Sigma \subseteq \Sigma_G \times \Sigma_L$, and $\Sigma$ is closed under decomposition.

The laws of commutativity and units follow directly from the fact that $*$ is the component-wise lifting of $*_G$ and $*_L$ on $\Sigma_G$ and $\Sigma_L$, and that $emp_G \times emp_L \subseteq \Sigma$.

To show associativity of $*$, let $s_1, s_2, s_3 \in \Sigma$ such that $s_2 \neq s_3$ and $s_1 \neq (s_2 * s_3)$. We have:

\[
s_1 * (s_2 * s_3) = (s_1.g * _G(s_2.g * _G s_3.g), s_1.l * _L(s_2.l * _L s_3.l)) \\
= ([s_1.g * _G s_2.g], [s_3.g], [s_1.l * _L s_2.l], [s_3.l]) = (s_1 * s_2) * s_3
\]

where the second equality follows by associativity of $*_G$ and $*_L$, and the third equality holds because $\Sigma$ is closed under decomposition.

The other direction follows by commutativity.

C FLOWS

The flow framework [41, 42] enables local reasoning about inductive properties of graphs. Intuitively, the framework views a heap as a (data) flow graph that induces flow constraints prescribing how flow values are propagated along the pointer edges of the heap. A flow is a solution to these flow constraints and assigns a flow value to every node in the graph. For instance, one can define a path-counting flow that computes for every node $x$ the number of paths that reach $x$ from some dedicated root node. By imposing an appropriate invariant on the flow at every node, one can then express inductive properties about the heap. For example, using the path-counting flow one can capture structural invariants such as that a heap region forms a list, a tree, or a DAG.

Flow graphs are endowed with a separation algebra that extends disjoint composition of heap graphs $h_1 * h_2$ with a stronger definedness condition. This stronger condition ensures that the flow of $h_1 * h_2$ is also the union of the flows of $h_1$ and $h_2$. This separation algebra admits frame rules.
that capture whether a local update of the heap graph \( h_1 \) preserves the flow of the context \( h_2 \) (and hence the flow-based inductive invariant of \( h_1 \circ h_2 \)).

In the following, we develop a new meta theory of flows that, unlike \([41, 42]\), is geared towards automatic inference of flow invariants, yielding a flow-based abstract domain for program analysis.

**Separation Algebra.** For a commutative monoid \( (\mathbb{M}, +, 0) \) we define the binary relation \( \leq \) on \( \mathbb{M} \) as \( n \leq m \) if there is \( o \in \mathbb{M} \) with \( m = n + o \). Flow values are drawn from a flow monoid, which is a commutative monoid for which the relation \( \leq \) is a complete partial order. In the following, we fix a flow monoid \( (\mathbb{M}, +, 0) \).

Let \( \text{Mon}(\mathbb{M} \to \mathbb{M}) \) be the monotonic functions in \( \mathbb{M} \to \mathbb{M} \). We lift + and \( \leq \) to functions \( \mathbb{M} \to \mathbb{M} \) in the expected way. An iterated sum over an empty index set \( \sum_{i \in \emptyset} m_i \) is defined to be 0.

A flow constraint is a tuple \( c = (X, E, \text{in}) \) consisting of a finite set of variables \( X \subseteq \text{Addr} \), a set of edges \( E : X \times \text{Addr} \to \text{Mon}(\mathbb{M} \to \mathbb{M}) \) labeled by monotonic functions, and an inflow \( \text{in} : (\text{Addr} \setminus X) \times X \to \mathbb{M} \). We use \( \text{FC} \) for the set of all flow constraints and denote the empty flow constraint by \( c_\emptyset \triangleq (\emptyset, \emptyset, \emptyset) \).

We define two derived functions for flow constraints. The flow is the least function \( \text{flow} : X \to \mathbb{M} \) satisfying

\[
\text{flow}(x) = \text{in}(x) + \text{rhs}_x(\text{flow}) \quad \text{for all } x \in X.
\]

Here, \( \text{in}(x) \triangleq \sum_{y \in (\text{Addr} \setminus X)} \text{in}(y, x) \) is a monoid value and \( \text{rhs}_x \triangleq \sum_{y \in X} E_{(y,x)} \) is a monotone function from \( \text{Mon}(X \to \mathbb{M}) \to \mathbb{M} \). We also define the outflow \( \text{out} : X \times (\text{Addr} \setminus X) \to \mathbb{M} \) by \( \text{out}(x, y) \triangleq E_{(x,y)}(\text{flow}(x)) \).

Intuitively, a flow constraint \( c \) abstracts a heap graph \( h \) with domain \( cX \) whose contents induce the edge functions \( cE \). The inflow \( c\text{.in} \) captures the contribution of \( h \)'s context to \( c\text{.flow} \) and the outflow \( c\text{.out} \) is the contribution of \( c \) to the context's flow. In fact, if we abstract from the specific inflow of \( c \), we can view \( c \) as a transformer from inflows to outflows. We make this intuition formally precise later. However, let us first discuss some examples.

**Example 21.** Path-counting flows are defined over the flow monoid of addition on natural numbers extended with the first limit ordinal, \( \mathbb{N} \cup \{ \omega \} \). Here, + is defined to be absorbing on \( \omega \). Figure 10 shows two flow constraints \( c_1 \) and \( c_2 \) for this flow monoid together with their flows and outflows. For example, we have \( c_1\text{.flow}(y) = c_1\text{.in}(r, y) + \lambda_{id}(c_1\text{.flow}(x)) = 1 + 1 = 2 \). The flow of each node corresponds to the number of paths starting from \( r \) that reach the node in the combined graph (shown on the right).
shows the composition $10_{45}$ shows two flow constraints that abstract potential states of the Harris component is meant to provide ghost information about the heap graph component. As we are interested in automating the reasoning, we will not modify the ghost information by ghost code.

Our heap model is a product between heap graphs and flow constraints. The flow component

Flow Graphs. Our heap model is a product between heap graphs and flow constraints. The flow component is meant to provide ghost information about the heap graph component. As we are interested in automating the reasoning, we will not modify the ghost information by ghost code.

Example 22. For our linearizability proofs of concurrent search structures we use a flow that labels every data structure node $x$ with its $\text{inset}$, the set of keys $k'$ such that a thread searching for $k'$ traverses the node $x$. That is, the flow monoid is sets of keys, $\mathbb{P}(\mathbb{Z} \cup \{-\infty, \infty\})$, with set union as addition. Figure 11 shows two flow constraints that abstract potential states of the Harris list. The idea is that an edge leaving a node $x$ that stores a key $k$ is labeled by the function $\lambda_k$. This is because a search for $k' \in \mathbb{Z}$ will traverse the edge leaving $x$ if $k < k'$ or $x$ is marked. In the figure, $l$ and $r$ are assumed to be unmarked, storing keys 6 and 8, respectively. Node $t$ is assumed to be marked. Flow constraint $c_2$ can be thought as being obtained from $c_1$ by physically unlinking the marked node $t$.

To define the composition of flow constraints, $c_1 \ast c_2$, we proceed in two steps. We first define an auxiliary composition that may suffer from fake flows, local flows that disappear in the composition. The actual composition then restricts the auxiliary composition to rule out such fake flows. Definedness of the auxiliary composition requires disjointness of the variables in $c_1$ and $c_2$. Moreover, the outflow of one constraint has to match the inflow expectations of the other:

$$c_1 \# c_2 \text{ if } c_1.X \cap c_2.X = \emptyset$$

and $\forall x \in c_1.X. \forall y \in c_2.X. c_1.out(x, y) = c_2.in(x, y)$.

The auxiliary composition removes the inflow that is now provided by the other component, denoted by $c_1.in'$ and $c_2.in'$:

$$c_1 \uplus c_2 \triangleq (c_1.X \uplus c_2.X, c_1.E \uplus c_2.E, c_1.in' \uplus c_2.in')$$

$$c_1.in'(x, y) \triangleq (x \in c_3\cdot X \land c_3\cdot out(x, y) \neq 0) \land c_1.in(x, y).$$

To rule out fake flows, we incorporate a suitable equality on the flows into the definedness for the composition:

$$c_1 \# c_2 \text{ if } c_1 \# c_2 \land c_1.flow \uplus c_2.flow = (c_1 \uplus c_2).flow.$$

Only if the latter equality holds, do we have the composition $c_1 \ast c_2 \triangleq c_1 \uplus c_2$. It is worth noting that $c_1.flow \uplus c_2.flow \geq (c_1 \uplus c_2).flow$ always holds. What definedness really asks for is the reverse inequality.

Example 23. The right side of Figure 10 shows the composition $c_1 \ast c_2$ of the flow constraints $c_1$ (left) and $c_2$ (center). Note that if the edge $(x, z)$ is removed from $c_1$, then the composition is no longer defined since the flow of $\omega$ in the cycle formed by $z, u, \omega$ and $v$ becomes a fake flow that vanishes in the flow constraint $c_1 \uplus c_2$ (the flow for $z, u, \omega$ and $v$ becomes 0).

Lemma 24. $\text{(FC} \ast, \{ c_\emptyset \})$ is a separation algebra.
but provide a mechanism to generate the flow constraint from the heap graph. This allows us to keep the flow constraint largely implicit.

Heap graphs $h \in HG$ are as defined in Example 19.

**Lemma 25.** $(HG, *, \{ h_\circ \})$ is a separation algebra.

To relate heap graphs and flow constraints, we classify selectors as data and pointer selectors, $Sel = DSel \uplus PSel$, and also write a heap graph $(X, sval)$ as $(X, dval, pval)$. Only pointer selectors will induce edges in a flow constraint via which we forward flow values. The data selectors will be used to determine the edge function. To this end, we assume to be given a generator for the edge functions:

$$gen : PSel \to (DSel \to Val) \to \text{Mon}(\mathbb{M} \to \mathbb{M})$$

It takes a pointer selector and a valuation of the data selectors and returns a monotonic function over the monoid of flow values. The generator is a parameter to our development, like the flow monoid and the sets of data and pointer selectors.

*Example 26.* For the Harris list we have a single pointer selector $next$ and data selectors $mark$ and $key$ storing the mark bit and key of a node, respectively.\(^1\) In order to obtain the edge functions that abstract the Harris list as described in Example 22, we use the following generator:

$$gen(next, dval) \triangleq dval(key) = -\infty \land m.(\mathbb{R}, \infty] : \lambda dval(key)$$

Recall that the condition $dval(key) = -\infty$ only holds for the head node. We use it here to fix the flow leaving head to the constant interval $(-\infty, \infty]$.

A flow graph is a pair $fg = (h, c)$ consisting of a heap graph $h$ and a flow constraint $c$ so that the nodes of the heap graph and flow constraint coincide, $h.X = c.X$, and so that $c.E$ is induced by $h.pval$ and $h.dval$ via $gen$. Being induced means that for all $x \in c.X$ and $y \in Addr$:

$$c.E(x, y) = \sum_{psel \in PSel : y = h.pval(x, psel)} gen(psel, h.dval(x))$$

Recall that empty sums are defined to be 0. The edge function iterates over all pointer selectors that lead from the source to the target node. It sums up the monoid functions given by the generator. Note that the edge functions are independent of the target node.

*Example 27.* Assuming the generator $gen$ from the previous example, $(h_1, c_1)$ is a flow graph where $c_1$ is as depicted in Figure 11:

$h_1.pval = \{ (l, next) \mapsto t, (t, next) \mapsto r, (r, next) \mapsto u \}$

$h_1.dval = \{ (l, mark) \mapsto false, (t, mark) \mapsto true \}$

$\forall \{ (r, mark) \mapsto false \}$

$\forall \{ (l, key) \mapsto 6, (t, key) \mapsto 7, (r, key) \mapsto 8 \}$.

We use $FG$ for the set of all flow graphs. It is a subset of the product separation algebra between the heap graphs and the flow constraints, $FG \subseteq HG \times FC$. This gives flow graphs a notion of definedness: $fg_1 \# fg_2$, if $fg_1.h \# fg_2.h$ and $fg_1.c \# fg_2.c$. They also inherit the component-wise composition in case definedness holds: $fg_1 \cdot fg_2 \triangleq (fg_1.h \cdot fg_2.h, fg_1.c \cdot fg_2.c)$. With this definition, we obtain a submonoid.

**Lemma 28.** $(FG, *, \{ (h_\circ, c_\circ) \})$ is a separation algebra.

\(^1\)Technically, the mark bit is encoded in the value of $next$. We here treat them separately for the sake of exposition.
Commands and Frame-Preserving Updates. Let \((h_1, c_1)\) be a flow graph and suppose that a command \(c\) updates the heap graph \(h_1\) to a new heap graph \(h_2\). Then the heap update induces a corresponding update of the flow constraint \(c_1\) to the flow constraint \(c_2\) generated from \(h_2\). For instance, consider the flow graph \((h_1, c_1)\) from Example 27. The heap \(h_2\) obtained by executing the command \(l.\text{next} := r\) generates the flow constraint \(c_2\) shown in Figure 11.

In order to ensure that the semantics of commands satisfies the locality condition (LocCom) assumed in §3, which is critical for the soundness of the frame rule, we need to ensure that the induced updates of the flow constraints are frame-preserving with respect to flow constraint composition. That is, if we have \(c_1 \neq c\) and we exchange \(c_1\) by \(c_2\), does \(c_2 \neq c\) still hold? Intuitively, \(c_2 \neq c\) still holds if \(c_1\) and \(c_2\) transform inflows to outflows in the same way.

Formally, for a flow constraint \(c\) we define its transfer function \(tf(c)\) mapping inflows to outflows,

\[
\text{tf}(c) : \left( (\text{Addr} \setminus X) \times X \rightarrow \mathbb{M} \right) \rightarrow X \times (\text{Addr} \setminus X) \rightarrow \mathbb{M},
\]

by \(\text{tf}(c)(\text{in'}) \triangleq c[\text{in} \mapsto \text{in'}].\text{out}\). For a given inflow \(\text{in}\), we may also write \(\text{tf}(c_1) =_{\text{in}} \text{tf}(c_2)\) to mean that for all inflows \(\text{in'} \leq \text{in}\), we have \(\text{tf}(c_1)(\text{in'}) = \text{tf}(c_2)(\text{in'})\).

For example, we have \(\text{tf}(c_1) =_{\text{in}} \text{tf}(c_2)\) for the flow constraints \(c_1\) and \(c_2\) in Figure 11. This is due to \(c_1.\text{in}(x) = \emptyset\) for all \(x \neq l\) and \(\lambda_6 \circ \lambda_{-\infty} = \lambda_6\). Observe that \(c_2\) composes with any frame \(c\) that \(c_1\) composes with. This captures the fact that physically unlinking the marked node \(t\) does not affect the remaining state of the data structure. The following lemma generalizes this observation. Its proof relies on Bekic’s lemma [5] and can be found in Appendix H.

Lemma 29. Assume \(c_1 \neq c\), \(c_1.X = c_2.X\), \(c_1.\text{in} = c_2.\text{in}\), and \(\text{tf}(c_1) =_{\text{in}} \text{tf}(c_2)\). Then (i) \(c_2 \neq c\) and (ii) \(\text{tf}(c_1 \circ c) =_{(c_1 \circ c).\text{in}} \text{tf}(c_2 \circ c)\).

In Appendix D we develop a semantics of a simple imperative programming language that satisfies the locality condition assumed in §3. Global states \(\Sigma_G\) and local states \(\Sigma_L\) are obtained by taking the product between flow graphs and variable valuations. The variable valuations track the values of both (immutable) program variables as well as logical variables. The construction of the state monoid \(\Sigma \subseteq \Sigma_G \times \Sigma_L\) is mostly standard and similar to the one discussed in Example 19. The semantics aborts a heap update \(c\) if its induced flow constraint update does not satisfy the frame preservation condition identified in Lemma 29.

D INSTANTIATION

In this section, we instantiate the developed program logic to a simple imperative programming language whose states consist of flow graphs.

In the following, we write flow graphs as \(fg = (X, \text{val}, \text{in})\). This goes without loss of generality since the nodes coincide for the heap graph and the flow constraint, and the edge function of the flow constraint is induced by the data and pointer selector valuations. For notational convenience, we also access the flow value by \(fg.\text{flow}\) rather than \(fg.c.\text{flow}\).

D.1 States

Valuations of program variables \(Y\), or simply stacks, stem from \(\text{Val}(Y) \triangleq Y \rightarrow \mathbb{N}\). Stacks are never split, \(\text{val}_1 \neq \text{val}_2\) is defined as \(\text{val}_1 = \text{val}_2\).

Lemma 30. \((\text{Val}(Y), *, \text{Val}(Y))\) is a separation algebra.

As we divide states into a global and a local component, we distinguish between a global program variables from the finite set \(\text{GPVar}\) and local variables from the disjoint and also finite set \(\text{LPVar}\). We use \(px, qx \in \text{PVar} = \text{GPVar} \cup \text{LPVar}\) to refer to variables that are either global or local. The separation algebra of global states is the product \(\Sigma_G \triangleq \text{FG} \times \text{Val}(\text{GPVar})\). Similarly, the separation
algebra of local states is the product $\Sigma_L \triangleq FG \times Val(LPVar)$. The set of states is a subset of the product separation algebra:

$$\Sigma \triangleq \{ (g, l) \in \Sigma_G \times \Sigma_L \mid \text{wellsplit}(g, l) \}.$$ 

Here, the predicate \text{wellsplit}(g, l) says that it is possible to combine the global and the local heap. Moreover, the global state does not point into the local heap. Formally,

$$\text{wellsplit}(g, l) \text{ if } g, lg \neq g, lg \wedge \forall px \in GPVar. g, val(px) \notin l, fg \wedge \forall a \in g, fg, X. \forall sel \in Sel. g, fg, sval(a, sel) \notin l, fg, X.$$ 

The assumptions made by Lemma 1 follow from the next lemma.

**Lemma 31.** For all $(g, l) \in \text{emp}_G \times \text{emp}_L$, \text{wellsplit}(g, l) holds. Furthermore, for all $g_1, g_2 \in \Sigma_G$ and $l_1, l_2 \in \Sigma_L$, if we have \text{wellsplit}$(g_1 * g_2, l_1 * l_2)$, then also \text{wellsplit}(g_1, l_1).

**Corollary 32.** $(\Sigma, *, \text{emp}_G \times \text{emp}_L)$ is a separation algebra.

To fix the notation, we write $s, fg$ for $s, g, fg * s, l, fg$ and similarly $s, val$ for $s, g, val \cup s, l, val$. Moreover, we denote $s, fg, h$ by $s, h$ and introduce a similar short-hand for $s, fg, c$.

When we modify the valuations of program variables and selectors, the result is not necessarily well-split. We introduce the following function that turns a pair of global and local state into a state that is well-split:

$$\text{split} : \Sigma_G \times \Sigma_L \rightarrow \Sigma.$$ 

The idea is to move the nodes from the local heap that are reachable from the shared state to the shared heap. The function is partial because the nodes from the local heap may in turn point outside the state, in which case the effect would not be limited to the state. Definedness of the function is as follows:

$$(g, l) \triangleq \text{split} \text{ if } g, fg \neq g, fg \text{ and } \forall a \in l, fg, X \forall px \in GPVar. \forall b \in g, fg, X \forall sel \in Sel. px \text{ reaches } a \lor b \text{ reaches } a \Rightarrow l, fg, sval(a, sel) \in l, fg, X \cup g, fg, X$$

The reachability predicate $px \text{ reaches } a$ resp. $b \text{ reaches } a$ is defined by either directly referencing address $a$ (in the case of $b$ through a selector) or by referencing an address that in turn reaches $a$. The formal definition is via a least fixed point. If defined, we set $\text{split}(g, l) \triangleq s$ with $s, fg = g, fg * l, fg, s, val = g, val \cup l, val, g, fg, X \subseteq s, g, fg, X$. Moreover, $s, l, fg$ is the maximal (wrt. inclusion on $s, g, X$) flowgraph that satisfies these constraints. The function is well-defined in that it uniquely determines a state and the state does exist. To see this, note that the state can be obtained by a least fixed point iteration that moves local nodes into the shared heap.

**Lemma 33.** $\text{split}(g, l)$ is well-defined.

We will need that $\text{split}$ is a local function. To formulate this, we define state modifications of the form $[px \mapsto a]$ and $[(a, sel) \mapsto b]$. This will modify the corresponding component in the state. The component will be clear from the type of the modification. For example, $s[(a, sel) \mapsto b]$ will modify the valuation $sval$ at the selector sel of address $a$. Since the flow graphs in the global and in the local state can be composed, only one of them will hold the address.

The modification itself should also have a local effect. To formulate this, we introduce updates

$$\text{up} : \mathbb{N} \times \mathbb{N} \rightarrow \text{Mon}(\mathcal{M} \rightarrow \mathcal{M})$$
as commands for changing flow constraints \( c \), which we then subsequently relate to the updates of heap graphs. The application of the update yields the new flow constraint

\[
\{ c[up] \} \triangleq (c.X, E, c.in)
\]

where the edges are defined by \( E(x, y) \triangleq up(x, y) \) if \( up \) is defined on \( (x, y) \) and \( E(x, y) \triangleq c.E(x, y) \) otherwise. Note that neither the nodes nor the inflow change. In Figure 11, e.g., we have \( c_2 = c_1[up] \) for \( up = \{(l, t) \mapsto \lambda_{\text{co}}, (l, r) \mapsto \lambda_{\text{lo}}\} \).

When considering updates as commands, we let the semantics abort should the update not be defined on the flow constraint or should it change the transformer. Using Lemma 29, this makes the semantics suitable for framing:

\[
\llbracket up\rrbracket(c) \triangleq \begin{cases} c[up] & \text{if } \text{dom}(up) \subseteq c.X \times \mathbb{N} \land tf(c) = c.in \text{ and } tf(c[up]) \\ \text{abort} & \text{otherwise.} \end{cases}
\]

The interplay between the semantics of updates and composition is captured by the following lemma. It ensures that the locality condition assumed in §3 is satisfied, once we tie flow constraint updates to updates on the heap graphs from which the flow constraints are derived.

**Lemma 34.** Let \( \llbracket up\rrbracket(c) \neq \text{abort} \) and \( c \neq c' \). Then we have:

(i) \( \llbracket up\rrbracket(c) \neq c' \) and

(ii) \( \llbracket up\rrbracket(c \ast c') = (c \ast c')[up] \) and

(iii) \( \llbracket up\rrbracket(c \ast c') \neq \text{abort} \) and

(iv) \( \llbracket up\rrbracket(c \ast c') = \llbracket up\rrbracket(c) \ast c' \).

We can now associate with a modification \( [(a, sel) \mapsto b] \) an update \( up \) of the state’s flow constraint \( s.c \). Here, we use \( s[(a, sel) \mapsto b] \) to denote the fact that the update induced by the modification does not abort on the flow constraint, \( \llbracket up\rrbracket(s.c) \neq \text{abort} \).

**Lemma 35.** If we have

- \( s \# s' \),
- \( a \in s.g \cdot fg \cdot X \Rightarrow b \in s.fg \cdot X \),
- \( s \# [(a, sel) \mapsto b] \), and
- \( s[(a, sel) \mapsto b] \# \text{split} \),

then we get

- \( (s \ast s') \# [(a, sel) \mapsto b] \),
- \( (s \ast s')[(a, psel) \mapsto b] \# \text{split} \), and
- \( \text{split}((s \ast s')[(a, sel) \mapsto b]) = \text{split}(s[(a, sel) \mapsto b]) \ast s' \).

The latter separating conjunction is defined.

**Proof.** We have \( (s \ast s') \# [(a, sel) \mapsto b] \) by Lemma 34(iii).

Moreover, \( (s \ast s')[(a, sel) \mapsto b] = s[(a, sel) \mapsto b] \times s' \) by Lemma 34(iv). The product on the right hand side of the previous equality denotes the separating conjunction applied componentwise, on the global and on the local state. It does not take into account well-splitting. If \( a \in s.l.fg \cdot X \), there is no splitting to be done and we obtain

\[
\text{split}((s \ast s')[(a, sel) \mapsto b]) = (s \ast s')[(a, sel) \mapsto b]
\]

(No splitting) } \Rightarrow (s \ast s')[(a, sel) \mapsto b] \times s'

(above) } \Rightarrow s[(a, sel) \mapsto b] \ast s'

(No splitting) } \Rightarrow \text{split}(s[(a, sel) \mapsto b]) \ast s' \]
If $a \in s.g.fg.X$, we have $b \in s.fg.X$. Since $s, s'$ are states, they are well-split and so the global part of each state does not point into the local heap of that state. Moreover, since $s \neq s'$ by the assumption, the global part of state $s'$ does not point into the local heap of $s$. With the same argument, the global part of $s$ does not point into the local heap of $s'$.

If $b \in s.g.fg.X$, this continues to hold for $s[(a, sel) \mapsto b]$.

If $b \in s.l.fg.X$, this continues to hold for $s[(a, sel) \mapsto b]$ as well, because $s[(a, sel) \mapsto b] \neq \text{split}$.

The definedness says that no local node from $s[(a, sel) \mapsto b]$ reachable from the global part points outside $s[(a, sel) \mapsto b]$, in particular $b$. Note that traversing $b$ is the only way to reach a local node from the global part in $s[(a, sel) \mapsto b]$. With the above discussion, splitting the state

$$(s \ast s')[(a, sel) \mapsto b] = s[(a, sel) \mapsto b] \times s'$$

will only move reachable nodes from $s.l.fg$ through $b$ to the global part. Since $s[(a, sel) \mapsto b] \neq \text{split}$, no such local node from $s[(a, sel) \mapsto b]$ that is reachable through $b$ points outside $s[(a, sel) \mapsto b]$. Hence $(s \ast s')[(a, psel) \mapsto b] \neq \text{split}$.

Splitting will add a new flow graph $fg^*$ to the shared heap of $(s \ast s')[(a, psel) \mapsto b]$. The result is

$$(s \ast s')[(a, psel) \mapsto b].g.fg \ast fg^*$$

$$(1)\Rightarrow (s[(a, psel) \mapsto b] \times s').g.fg \ast fg^*$$

$$(2)\Rightarrow s[(a, psel) \mapsto b].g.fg \ast s'.g.fg \ast fg^*$$

$$(3)\Rightarrow (s[(a, psel) \mapsto b].g.fg \ast fg^* \ast s'.g.fg).$$

where the qualities follow from (1) the above discussion, (2) componentwise separating conjunction, and (3) commutativity. This is the shared heap of $\text{split}(s[(a, sel) \mapsto b])$ composed with the shared heap of $s'$. For the local heap, we already discussed above that we only move nodes from $s.l.fg$. Hence, $s'$ remains unchanged. \hfill \Box

For modifications of program variables, there is a related result. Since stacks are not split, however, the modification applies to both states of the separating conjunction.

**Lemma 36.** Consider $s \neq s'$ and $px \in GPVar \Rightarrow b \in s.fg.X$ and $s[px \mapsto b] \neq \text{split}$. Then we have $(s \ast s')[px \mapsto b] \neq \text{split and split}((s \ast s')[px \mapsto b]) = \text{split}(s[px \mapsto b]) \ast s'[px \mapsto b]$. The latter separating conjunction is defined.

**Proof.** Assume $px \in GPVar$, otherwise there is no splitting. We have

$$(s \ast s')[px \mapsto b] = s[px \mapsto b] \ast s'[px \mapsto b]$$

since stacks are not split. The claim then follows with an argumentation similar to the one in the previous lemma. \hfill \Box

We also have a modification that corresponds to an allocation. For defining allocations, we introduce the initial flow graph for address $a \in \mathbb{N}$, which is

$${\text{initfg}}(a) \triangleq \{(a), \{ (a, sel, a) \mid sel \in Sel \}, \{ (b, \lambda_0, a) \mid b \in \mathbb{N} \setminus \{a\} \}) .$$

In the latter set, $\lambda_0$ is the constant 0 function. Every selector points to the fresh node and the inflow is 0 on all incoming edges. Allocation is then captured by the function

$${\text{ext}} : \Sigma \times \mathbb{N} \rightarrow \Sigma.$$

It extends the local flow graph by an initial flow graph for the given address. The function yields

$${\text{ext}}(s, a) \triangleq (s.g, (s.l.fg \ast {\text{initfg}}(a), s.l.val)) .$$
We use the notation \[ \text{ALVar} \]

The semantics of commands is given in Figure 12. Semantics of commands.

It is defined only if the address is fresh, \( a \not\in s.fg.X \), and not pointed to from a global variable or the global heap of \( s \). We denote this definedness by \( (s, a) \notin \text{ext} \). The result is well-split.

**Lemma 37.** If \( (s, a) \notin \text{ext} \) then \( \text{ext}(s, a) \in \Sigma \).

### D.2 Commands

The set of **commands** is:

\[
\text{com ::= } \text{skip} \mid px := \text{aop}(qx_1, \ldots, qx_n) \mid px := qx \rightarrow \text{sel} \mid px \rightarrow \text{sel} := qx \\
\mid px := \text{malloc} \mid \text{assume pred}(px_1, \ldots, px_n) \mid \text{assert pred}(px_1, \ldots, px_n).
\]

Here, \( px, qx \in \text{PVar} \) are program variables, \( \text{sel} \in \text{Sel} \) is a selector, and \( \text{aop} : \mathbb{N}^n \rightarrow \mathbb{N} \) and \( \text{pred} : \mathbb{N}^n \rightarrow \mathbb{B} \) are an operation resp. a predicate over the address domain.

The semantics is strict in abort:

\[
\llbracket \text{com} \rrbracket(\text{abort}) \triangleq \{ \text{abort} \}.
\]

For a state \( s \neq \text{abort} \), we define the following preconditions:

\[
\begin{align*}
\text{assignfromop} & \triangleq \ b = \llbracket \text{aop}(px_1, \ldots, px_n) \rrbracket \text{ s.val} \\
& \quad \land (px \in \text{GPVar} \Rightarrow b \in s.fg.X) \land s[px \mapsto b] \# \text{split} \\
\text{assignfromsel} & \triangleq \ a = \llbracket qx \rrbracket \text{ s.val} \land a \in s.fg.X \land b = \text{val}(a, \text{sel}) \\
& \quad \land (px \in \text{GPVar} \Rightarrow b \in s.fg.X) \land s[px \mapsto b] \# \text{split} \\
\text{assigntosel} & \triangleq \ a = \llbracket px \rrbracket \text{ s.val} \land b = \llbracket qx \rrbracket \text{ s.val} \land s[#(a, \text{sel}) \mapsto b] \\
& \quad \land (a \in s.fg.g.X \Rightarrow b \in s.fg.X) \land s[(a, \text{sel}) \mapsto b] \# \text{split}.
\end{align*}
\]

We use the notation \( \text{condition} \) \( \text{value} \) as a short hand for the expression \( \text{condition} \ ? \text{value} : \{ \text{abort} \} \).

The semantics of commands is given in Figure 12.

### D.3 Assertions

We use countable sets \( \text{ALVar} \) and \( \text{FLVar} \) of logical variables with typical elements \( ax \) resp. \( fx \). The first set holds variables that store addresses, the second holds variables for flow values. The logical variables are assumed to be disjoint and disjoint from the program variables. We use

\[
\text{LogVal} \triangleq (\text{ALVar} \rightarrow \mathbb{N}) \cup (\text{FLVar} \rightarrow \mathbb{M})
\]

for the set of all valuations of the logical variables that respect the typing. We write

\[
\text{ProgLogVal} \triangleq \text{Val}(\text{LPVar}) \cup \text{Val}(\text{GPVar}) \cup \text{LogVal}
\]

for all valuations of the program and logical variables.
A Concurrent Program Logic with a Future and History 37

An address term is an address term. The definition is as follows:

- \(fg, plv \models emp\) if \(fg.X = \emptyset\)
- \(fg, plv \models pred(\text{term}_1, \ldots, \text{term}_n)\) if \(\text{pred}(\llbracket \text{term}_1 \rrbracket plv, \ldots, \llbracket \text{term}_n \rrbracket plv)\)
- \(fg, plv \models a\text{term}_1 \mapsto_{\text{sel}} a\text{term}_2\) if \(\exists a, b. \ a = \llbracket a\text{term}_1 \rrbracket plv \wedge b = \llbracket a\text{term}_2 \rrbracket plv \wedge \text{fg}.X = \{a\} \wedge \text{fg}.\text{sel}(a, \text{sel}) = b\)
- \(fg, plv \models a\text{term} \mapsto_{\text{in}} f\text{term}\) if \(\exists a, m. \ a = \llbracket a\text{term} \rrbracket plv \wedge m = \llbracket f\text{term} \rrbracket plv \wedge \text{fg}.X = \{a\} \wedge \text{fg}.\text{in}(a) = m\)
- \(fg, plv \models a\text{term} \mapsto_{\text{flow}} f\text{term}\) if \(\exists a, m. \ a = \llbracket a\text{term} \rrbracket plv \wedge m = \llbracket f\text{term} \rrbracket plv \wedge \text{fg}.X = \{a\} \wedge \text{fg}.\text{flow}(a) = m\).

Fig. 13. Satisfaction relation for atomic predicates.

Terms are either address terms of type \(\mathbb{N}\) or flow terms of type \(\mathbb{M}\). We write \(\mathbb{D}\) to mean either \(\mathbb{N}\) or \(\mathbb{M}\). To form terms, we assume the address domain and the flow domain each come with a set of operations \(\text{AOP}\) resp. \(\text{FOP}\) defined on them. Each operation has a type. For address operations, this type has the form \(\mathbb{D}_1 \rightarrow \cdots \rightarrow \mathbb{D}_n \rightarrow \mathbb{N}\). For flow operations, the result is a monoid value. To ease the notation, we simplify the types to \((\mathbb{N} \cup \mathbb{M})^n \rightarrow \mathbb{D}\) and write \(\text{term}\) for an address or a flow term. In applications, we will respect the precise types. We also assume to have a set of predicates \(\text{Pred}\) that follow a similar typing scheme.

The sets of address and flow terms are defined by mutual induction:

- \(a\text{term} \ ::= \ a \mid ax \mid px \mid \text{aop}(\text{term}_1, \ldots, \text{term}_n)\)
- \(f\text{term} \ ::= \ m \mid fx \mid \text{fop}(\text{term}_1, \ldots, \text{term}_n)\).

An address term is an address \(a \in \mathbb{N}\), a logical address variable \(ax \in \text{ALVar}\), a program variable \(px \in \text{PVar}\), and an operation \(\text{aop} \in \text{AOP}\) applied to \(n\) terms, with \(n\) is the operation’s arity. A flow term is a flow value \(m \in \mathbb{M}\), a logical flow variable \(fx \in \text{FLVar}\), and a flow operation \(\text{fop} \in \text{FOP}\) applied to terms.

The semantics expects a valuation \(plv\) of the program and logical variables and returns an address or flow value:

\[\llbracket \text{term} \rrbracket : \text{ProgLogVal} \rightarrow \mathbb{N} \cup \mathbb{M} .\]

The definition is as follows:

\[\llbracket d \rrbracket \ plv \triangleq d \quad \llbracket x \rrbracket \ plv \triangleq plv(x) \quad \llbracket \text{op}(\text{term}_1, \ldots, \text{term}_n) \rrbracket \ plv \triangleq \text{op}(\llbracket \text{term}_1 \rrbracket \ plv, \ldots, \llbracket \text{term}_n \rrbracket \ plv) .\]

Here, \(d\) is an address \(a \in \mathbb{N}\) or a flow value \(m \in \mathbb{M}\), \(x\) is a logical flow variable \(fx \in \text{FLVar}\), a logical address variable \(ax \in \text{ALVar}\), or a program variable \(px \in \text{PVar}\), and \(\text{op}\) is a flow operation \(\text{fop} \in \text{FOP}\) or an address operation \(\text{aop} \in \text{AOP}\).

The set of atomic predicates is defined as follows, with \(sel \in \text{Sel}\):

\[\text{apred} \ ::= \ emp \mid \text{pred}(\text{term}_1, \ldots, \text{term}_n) \mid a\text{term}_1 \mapsto_{\text{sel}} a\text{term}_2 \mid a\text{term} \mapsto_{\text{in}} f\text{term} \mid a\text{term} \mapsto_{\text{flow}} f\text{term}.\]

A flow graph \(fg\) and a valuation \(plv\) of the program and logical variables satisfy an atomic predicate as prescribed by Figure 13.

The set of state predicates is defined by

\[A \ ::= \ \text{apred} \mid \neg A \mid A_1 \land A_2 \mid \exists a. A \mid \exists fx. A \mid A_1 * A_2 \mid A_1 \rightarrow A_2 \mid A.\]
It will be convenient to have the box predicate $A$ as introduced in RGSep [61, 65]. The predicate is meant to describe constraints over the shared state. Therefore, we expect $A$ to contain neither local program variables nor further boxes.

The abort state never satisfies a state predicate.

For states $s = (g, l) \in \Sigma$ and valuations $lv$ of the logical variables that occur free in the formula the satisfaction relation is defined as follows:

$$
\begin{align*}
  s, lv \models \text{apred} & \quad \text{if} \quad s.l.fg, lv \cup s.val \models \text{apred} \\
  s, lv \models \neg A & \quad \text{if} \quad s, lv \not\models A \\
  s, lv \models A_1 \land A_2 & \quad \text{if} \quad s, lv \models A_1 \land s, lv \models A_2 \\
  s, lv \models \exists ax.A & \quad \text{if} \quad \exists a \in \mathbb{N}. s, lv[ax \mapsto a] \models A \\
  s, lv \models \exists fx.A & \quad \text{if} \quad \exists m \in \mathbb{M}. s, lv[fx \mapsto m] \models A \\
  s, lv \models A_1 \rightarrow A_2 & \quad \text{if} \quad \forall s'. (s \# s' \land s', lv \models A_1) \Rightarrow s \ast s', lv \models A_2 \\
  s, lv \models A & \quad \text{if} \quad s.l \in \text{emp}_l \land s.g, lv \models \=' A.
\end{align*}
$$

The definition of $\models \='$ is similar. The key difference is that we split the global flow graph when defining the separating conjunction, and similar for the separating implication. Note that by the assumption on the shape of formulas, we do not need a valuation of the local variables to determine the truth of atomic predicates that occur inside boxes.

The set of computation predicates is

$$
C ::= \_A \mid \Diamond A \mid C \land C \mid C \lor C \mid C \cdot C \mid \exists ax.C \mid \exists fx.C.
$$

The semantics is defined over non-empty sequences $\sigma$ with $\sigma \in (\Sigma \cup \{\text{abort}\})^\ast$ and valuations of logical variables $lv$ as follows. A sequence containing abort never satisfies a predicate. For a sequence $\sigma \in \Sigma^\ast$, we define:

$$
\begin{align*}
  \sigma.s, lv \models \_A & \quad \text{if} \quad s, lv \models A \\
  \sigma, lv \models \Diamond A & \quad \text{if} \quad \exists s \in \Sigma, \sigma_1, \sigma_2 \in \Sigma^\ast, \sigma = \sigma_1.s.\sigma_2 \land s, lv \models A \\
  \sigma, lv \models C_1 \land C_2 & \quad \text{if} \quad \sigma, lv \models C_1 \land \sigma, lv \models C_2 \\
  \sigma, lv \models C_1 \lor C_2 & \quad \text{if} \quad \sigma, lv \models C_1 \lor \sigma, lv \models C_2 \\
  \sigma, lv \models C_1 \ast C_2 & \quad \text{if} \quad \sigma_1, \sigma_2 \in \Sigma^\ast, \sigma_1 \# \sigma_2 \land \sigma = \sigma_1 \ast \sigma_2 \land \sigma_1, lv \models C_1 \land \sigma_2, lv \models C_2 \\
  \sigma, lv \models \exists ax.C & \quad \text{if} \quad \exists a \in \mathbb{N}. \sigma, lv[ax \mapsto a] \models C \\
  \sigma, lv \models \exists fx.C & \quad \text{if} \quad \exists m \in \mathbb{M}. \sigma, lv[fx \mapsto m] \models C.
\end{align*}
$$

A computation predicate is closed if it does not contain free logical variables. In this case, the satisfaction relation only depends on the computation but is independent of the valuation. We write $[C]$ for the set of computations that satisfy a predicate. We need the following lemma, which is a consequence of Lemma 13 with the consideration of quantifiers added.

**Lemma 38.** $[C]$ is frameable for every $C$.

**Lemma 39.** If we have $\sigma.s \in [C]$ and $px \notin lv(C)$, then we also have $\sigma.s.(s[px \mapsto a]) \in [C]$.

In addition to the equivalences listed in Lemma 14, we have the following for quantifiers over logical variables.

**Lemma 40.** We have:

$$
\sigma, lv \models \exists ax._A \iff \sigma, lv \models \_(\exists ax.A) \quad \text{and} \quad \sigma, lv \models \exists fx._A \iff \sigma, lv \models \_(\exists fx.A).
$$
D.4 Semantics

With the development in Section 7, the semantics generalizes to computations. The key property required in Section 3 is as follows.

**Lemma 41.** Let \( \text{com} \) be different from \( px := \text{aop}(qx_1, \ldots, qx_n), px := qx \rightarrow \text{sel}, \) and \( px := \text{malloc}. \) Then \( \llbracket \text{com} \rrbracket(\llbracket C_1 \rrbracket) \subseteq \llbracket C_2 \rrbracket \) implies \( \llbracket \text{com} \rrbracket(\llbracket C_1 * C \rrbracket) \subseteq \llbracket C_2 * C \rrbracket. \)

**Proof.** Recall: \( \llbracket C_1 * C \rrbracket \) contains sequences of states \( \sigma.s \in \Sigma^+. \) It is readily checked that \( \llbracket C_1 * C \rrbracket = \llbracket C_1 \rrbracket * \llbracket C \rrbracket. \) So there are \( \sigma_1.s_1 \in \llbracket C_1 \rrbracket \) and \( \sigma_2.s_2 \in \llbracket C_2 \rrbracket \) with \( \sigma.s = \sigma_1.s_1 * \sigma_2.s_2. \) We have that \( \llbracket \text{com} \rrbracket(\sigma.s) \) extends the sequence \( \sigma.s \) by elements from \( \llbracket \text{com} \rrbracket(s). \) Such elements are either abort or states.

**Case abort.** We show that \( \llbracket \text{com} \rrbracket(s) = \text{abort} \) implies \( \llbracket \text{com} \rrbracket(s_1) = \text{abort}. \) Then \( \llbracket \text{com} \rrbracket(C_1) \) contains a sequence with abort, contradicting \( \llbracket \text{com} \rrbracket(\llbracket C_1 \rrbracket) \subseteq \llbracket C_2 \rrbracket. \) We distinguish the following cases:

- Skip and assume do not abort.
- An assertion only depends on the valuation of the program variables. Valuations are never split. This means \( s_1 \) will have the same valuation, and lead to the same abort.
- We have excluded assignments to program variables and malloc.
- An assignment to a selector aborts.

It remains to argue for the last case. An assignment to a selector aborts if the condition \( \text{assigntosel} \) fails. We consider each case and argue that the abort also happens on \( s_1. \) Note that valuations are never split, so the addresses \( a \) and \( b \) are the same in \( s_1. \) If \( s \nmid [(a, \text{sel}) \mapsto b] \) fails, we have \( \llbracket \text{up} \rrbracket(s.c) = \text{abort}, \) with \( \text{up} \) induced by \( [(a, \text{sel}) \mapsto b]. \) By Lemma 34 applied in contraposition, \( \llbracket \text{up} \rrbracket(s_1.c) = \text{abort}. \) The contraposition applies because \( s_1 \# s_2 \) implies \( s_1.c \# s_2.c \) and \( s_1.c * s_2.c = s.c. \) Hence, the command will abort on \( s_1. \)

If the implication \( a \in s.fg.g.X \Rightarrow b \in s.fg.g.X \) fails, we have \( a \in s.fg.g.X \) and \( b \notin s.fg.g.X. \) To see that the implication also fails on \( s_1, \) consider first the case that the implication becomes trivial, \( a \notin s_1.fg.g.X. \) Then \( \llbracket \text{up} \rrbracket(s_1.c) = \text{abort}, \) because the domain of the update induced by the modification is not included in the state. If the implication is non-trivial, \( b \notin s.fg.g.X \) implies \( b \notin s_1.fg.g.X. \) This is because of \( s.fg.X = s_1.fg.X \cup s_2.fg.X. \) Hence the implication, and so the command, also fail on \( s_1. \)

If \( s_1[(a, \text{sel}) \mapsto b] \) does not hold, then Lemma 35 applies in contraposition and yields a failure of definedness, \( s_1[(a, \text{sel}) \mapsto b] \) # split. A failure of \( s_1[(a, \text{sel}) \mapsto b] \) # split in turn means that the command aborts on \( s_1. \) To see that the contraposition applies, note that \( s_1 * s_2 = s. \) Moreover, we can rely on the implication \( a \in s_1.fg.g.X \Rightarrow b \in s_1.fg.g.X, \) for otherwise the command would abort on \( s_1. \) Similarly, if \( s_1 \nmid [(a, \text{sel}) \mapsto b] \) failed, we would also abort on \( s_1. \)

**Case \( s' \in \llbracket \text{com} \rrbracket(s). \)** We show that there is \( s_1' \in \llbracket \text{com} \rrbracket(s_1) \) with \( s_1' \# s_2 \) and \( s' = s_1' * s_2. \) Then \( \llbracket \text{com} \rrbracket(\llbracket C_1 \rrbracket) \subseteq \llbracket C_2 \rrbracket, \) \( \sigma_1.s_1 \in \llbracket C_1 \rrbracket, \) \( s_1' \in \llbracket \text{com} \rrbracket(s_1) \) imply \( \sigma_1.s_1.s_1' \in \llbracket C_2 \rrbracket. \) Since \( \llbracket C \rrbracket \) is frameable by Lemma 38, \( \sigma_2.s_2.s_2 \in \llbracket C \rrbracket. \) So, \( \sigma.s.s' = \sigma_1.s_1.s_1' * \sigma_2.s_2.s_2 \in \llbracket C_2 \rrbracket * \llbracket C \rrbracket = \llbracket C_2 * C \rrbracket. \) Case analysis:

- For skip, we have \( s' = s \) and \( s_1' = s_1 \in \llbracket \text{skip} \rrbracket(s_1). \) Then \( s' = s_1 * s_2. \)
- Assume and assert are similarly simple, as the semantics only depends on the program variable valuation and that is not split.
- We have excluded assignments and mallocs to program variables.
• For an assignment to a selector that results in the state $s' = \text{split}(s[(a, \text{sel}) \mapsto b])$, we have condition assigntosel for $s_1$ as follows:

$$a = [px]_{s_1.\text{val}} \land b = [qx]_{s_1.\text{val}} \land s_1[(a, \text{sel}) \mapsto b]$$

$$\land s_1[(a, \text{sel}) \mapsto b] \# \text{split} \land (a \in sfg.X \Rightarrow b \in sfg.X).$$

Otherwise, the assignment would abort on $s_1$, contradicting $\llbracket \text{com} \rrbracket([C_1]) \subseteq [C_2]$. When applied to $s_1$, we obtain $s'_1 = \text{split}(s_1[(a, \text{sel}) \mapsto b])$. Then

$$s'_1 \ast s_2 = \text{split}(s_1[(a, \text{sel}) \mapsto b]) \ast s_2$$

$$= \text{split}((s_1 \ast s_2)[(a, \text{sel}) \mapsto b]) = \text{split}(s[(a, \text{sel}) \mapsto b]) = s'$$

The first equality is the definition of $s'_1$, the next is Lemma 35, the third is the fact that $s_1 \ast s_2 = s$, and the last is the definition of $s'$. The lemma applies by assigntosel stated above. This concludes the proof.

Since we do not use program variables as resources, the above lemma will not hold without prerequisites for assignments to program variables and malloc. The prerequisite will be that the program variable modified by the command does not occur free in the predicate that is added with the separating conjunction. The prerequisite will then form a side-condition to applying the frame rule.

**Lemma 42.** Let $\text{com}$ be one of: $px := \text{aop}(qx_1, \ldots, qx_n)$ or $px := qx \rightarrow \text{sel}$ or $px := \text{malloc}$. Let $px \notin \text{fv}(C)$. Then we have: $\llbracket \text{com} \rrbracket([C_1]) \subseteq [C_2] \implies \llbracket \text{com} \rrbracket([C_1 + C]) \subseteq [C_2 + C]$.

**Proof.** The proof follows the same strategy as the proof for the previous lemma. Recall that $\llbracket C_1 + C \rrbracket$ contains sequences of states $\sigma.s \in \Sigma^+$. Hence, there are some $\sigma_1.s_1 \in [C_1]$ and $\sigma_2.s_2 \in [C_2]$ with $\sigma.s = \sigma_1.s_1 \ast \sigma_2.s_2$. Moreover, we have that $\llbracket \text{com} \rrbracket(\sigma.s)$ extends the sequence $\sigma.s$ by elements from $\llbracket \text{com} \rrbracket(s)$. Such elements are either abort or states.

**Case abort.** We are going to show that $\llbracket \text{com} \rrbracket(s) = \text{abort}$ implies $\llbracket \text{com} \rrbracket(s_1) = \text{abort}$. Then $\llbracket \text{com} \rrbracket(C_1)$ contains a sequence with abort, contradicting $\llbracket \text{com} \rrbracket([C_1]) \subseteq [C_2]$.

• Consider $px := \text{aop}(qx_1, \ldots, qx_n)$. It aborts due to a failure of the precondition assignfromop.

The expression will evaluate to the same address $b$ in $s_1$, because stacks are never split. Assume the implication fails, meaning $px \in \text{GPVar}$ and $b \notin sfg.X$. Then $b \notin s_1.fg.X$ as $s.fg.X = s_1.fg.X \cup s_2.fg.X$. Hence, the implication will also fail on $s_1$ and we have the desired abort.

If $s[px \mapsto b] \# \text{split}$ fails, then either the local and the global flow graph of $s[px \mapsto b]$ do not compose or we reach a local node from the global state that points to a node outside the state. In the former case, we note that $s[px \mapsto b].g.fg = s.g.fg$ and $s[px \mapsto b].l.fg = s.l.fg$. Moreover, we know that $s.g.fg \neq s.l.fg$ as states are well-split. The case does not occur.

In the latter case, the node that points outside $s$ is reachable through $b$. To see this, note that $s$ is well-split and hence there is no way for the global state to reach the local heap. In this case, split is defined (and the identity). Hence, the only way to make split fail is by following the pointer from $px$ to $b$ and potentially further to the mentioned node. In $s_1[px \mapsto b]$, we may be able to follow the same path, in which case split would also fail on $s_1[px \mapsto b]$ due to the same node. Alternatively, the path may lead outside $s_1[px \mapsto b]$. In that case, there is a first node on the path that leaves $s_1[px \mapsto b]$. This first node points outside $s_1[px \mapsto b]$, namely to the next node on the path. As a result, split also fails on $s_1[px \mapsto b]$, as required.
Consider $px := qx \rightarrow \text{sel}$. The command aborts due to a failure of the precondition $\text{assignfromsel}$. The command may abort as $a \notin \text{fg}.X$. Then $a \notin s_1.\text{fg}.X$ by $s_1.\text{fg}.X \uplus s_2.\text{fg}.X = s.\text{fg}.X$. Hence, the command will also abort on $s_1$.

For the implication and splitting, the argumentation is like in the previous case.

A malloc does not abort, so the case does not occur.

Case $s' \in \set{\text{com}}(s)$. We show there are $s'_1 \in \set{\text{com}}(s_1)$ and $s_2.\text{fg}.s'_2 \in \set{C}$ with $s'_1 \neq s'_2$ and $s' = s'_1 \ast s'_2$. From the former condition and the assumption, we get $s_1.s_1.s'_1 \in \set{C}_2$. Hence, $s.\text{fg}.s' = s_1.s_1.s'_1 \ast s_2.\text{fg}.s'_2 \in \set{C}_2 \ast \set{C} = \set{C} \ast \set{C}$. We distinguish the cases.

- Consider $px := \text{aop}(qx_1, \ldots, qx_n)$. The resulting state is $s' = \text{split}(s[px \mapsto b])$ with $b = \set{\text{aop}(px_1, \ldots, px_n)} s.\text{val}$.

The command does not abort on $s_1$, as this would contradict $\set{\text{com}}(\set{C}_1) \subseteq \set{C}_2$. Moreover, the valuations of the program variables will coincide for $s$ and $s_1$. Hence, address $b$ will not change and we get the precondition $\text{assignfromsel}$ for $s_1$:

$$b = \set{\text{aop}(px_1, \ldots, px_n)} s_1.\text{val} \land (px \in \text{GPVar} \Rightarrow b \in s_1.\text{fg}.X) \land s_1[px \mapsto b] \neq \text{split}.$$ 

The state resulting from the command is

$$s'_1 = \text{split}(s_1[px \mapsto b]).$$

Moreover, the precondition is strong enough to apply Lemma 36. With $s'_2 = s_2[px \mapsto b]$, the lemma shows $s'_1 \neq s'_2$ and $s' = s'_1 \ast s'_2$. For $s'_2$, Lemma 39 yields $s_2.\text{fg}.s'_2 \in \set{C}$. This concludes the case.

- Consider $px := qx \rightarrow \text{sel}$. The resulting state is this one: $s' = \text{split}(s[px \mapsto b])$ with $b = s.\text{val}(a, \text{sel})$ and $a = \set{qx} s.\text{val}$. The command does not abort on $s_1$, as this would contradict $\set{\text{com}}(\set{C}_1) \subseteq \set{C}_2$. Moreover, the valuations of the program variables will coincide for $s$ and $s_1$. Hence, address $a$ will not change and we get the precondition $\text{assignfromsel}$ for $s_1$:

$$a = \set{qx} s_1.\text{val} \land b' = s_1.\text{val}(a, \text{sel}) \land a \in s_1.\text{fg}.X \land s_1[px \mapsto b'] \neq \text{split} \land (px \in \text{GPVar} \Rightarrow b' \in s_1.\text{fg}.X).$$

Because $s = s_1 \ast s_2$ and $s_1.\text{val}(\cdot)$ is a function, we have $b' = b$. Hence, the state resulting from the command is $s'_1 = \text{split}(s_1[px \mapsto b])$. The remainder of the reasoning is as in the previous case.

- Consider $px := \text{malloc}$. The resulting state is $s' = \text{split}(\tilde{s}[px \mapsto b])$ with $\tilde{s} = \text{ext}(s, b)$. Since $(s, b) \neq \text{ext}$, we have $(s_1, b) \neq \text{ext}$. The address is fresh for $s_1$ as $s_1.\text{fg}.X \uplus s_2.\text{fg}.X = s.\text{fg}.X$ and the address is fresh for $s$. To see that the global part of $s_1$ does not point to the address, note that the global part of $s$ does not point to it and we have $s_1.g \ast s_2.g = s.g$. Hence, $(s_1, b) \neq \text{ext}$ and we let $\tilde{s}_1 = \text{ext}(s_1, b)$. With the same argument, also the global part of $s_2$ does not point to the address. The global part of $s_2$ does not point to the remaining local heap of $s_1$ as $s_1 \neq s_2$. With the same argument, the global part of $s_1$ does not point to the local heap of $s_2$. Hence, $\tilde{s}_1 \neq s_2$. Since $s_1 \ast s_2 = s$, we moreover have $\tilde{s}_1 \ast s_2 = \tilde{s}$.

Since $s_1$ is a state, it is well-split. By definition, $b$ only points to itself. Hence, we have $\tilde{s}_1[px \mapsto b] \neq \text{split}$ and set $s'_1 = \text{split}(\tilde{s}_1[px \mapsto b])$. The splitting will move $b$ to the shared heap should $px$ be a shared variable. Lemma 36 applies and yields $s'_1 \ast s'_2$ where we have $s'_1 = s_2[px \mapsto b]$. It is readily checked that $s'_1 \in \set{\text{malloc}}(s_1)$. Moreover, $s_2.\text{fg}.s'_2 \in \set{C}$ by Lemma 39.

This concludes the proof.
E PROOF OF THEOREM 3: SOUNDNESS OF THE PROGRAM LOGIC

The guarantee given by the thread-local proofs constructed in our program logic is captured by the notion of safety. Safety guarantees that upon termination the postcondition holds, acc(st, r, p) is defined as st = skip ⇒ r ⊆ p. Moreover, for every command to be executed we are sure to have captured the intermediate and to execute safely for another k steps from the resulting predicate.

**Definition 43.** We define safe_{P, i}^k(st, r, p) ≡ true and safe_{P, i}^{k+1}(st, r, p) ≡ (1) ∧ (2) with

1. acc(st, r, p)
2. ∀com.∀st'. st \xrightarrow{com} st' ⇒ inter(r, com) \subseteq I ∧ \exists n ∈ P. \llbracket com\rrbracket(r) \subseteq n ∧ safe_{P, i}^k(st', n, p).

The predicate is monotonic in the various arguments as follows.

**Lemma 44.** Consider P_1 ⊆ P_2, I_1 ⊆ I_2, p_1 ⊇ p_2, q_1 ⊆ q_2, and k_1 ≥ k_2. Then safe_{P, i_1}^{k_1}(st, p_1, q_1) implies safe_{P, i_2}^{k_2}(st, p_2, q_2).

**Proof.** Consider P_1 ⊆ P_2, I_1 ⊆ I_2, and q_1 ⊆ q_2.

We proceed by induction on k_1.

k_1 = 0: There is nothing to do.

k_1 + 1: The induction hypothesis is ∀k_2.∀st.∀p_1.∀p_2. k_2 ≤ k_1 ∧ p_1 ⊇ p_2 ∧ safe_{P, i_1}^{k_1}(st, p_1, q_1) ⇒ safe_{P, i_2}^{k_2}(st, p_2, q_2).

Further, consider st and p_1 so that safe_{P, i_1}^{k_1}(st, p_1, q_1). Consider k_2 ≤ k_1 + 1 and p_2 ⊆ p_1. We show safe_{P, i_2}^{k_2}(st, p_2, q_2).

We can assume 0 < k_2, otherwise there is nothing to do.

1. We have safe_{P, i_1}^{k_1+1}(st, p_1, q_1). Hence, if st = skip, then p_1 ⊆ q_1. We have p_2 ⊆ p_1 and q_1 ⊆ q_2 by assumption. Hence, p_2 ⊆ q_2 as required.

2a. Consider st = com, st'. We have safe_{P, i_1}^{k_1+1}(st, p_1, q_1). Hence, inter(p_1, com) ⊆ I_1. This means there is (o, com) ∈ I_1 with p_1 ⊆ o. We have p_2 ⊆ p_1 and so p_2 ⊆ o. Hence, inter(p_2, com) ⊆ I_1. We have I_1 ⊆ I_2 by assumption. Hence, inter(p_2, com) ⊆ I_2 as required.

2b. Because of safe_{P, i_1}^{k_1+1}(st, p_1, q_1), there is n ∈ P_1 as follows. We have \llbracket com\rrbracket(p_1) ⊆ n as well as safe_{P, i_1}^{k_1}(st', n, q_1). As P_1 ⊆ P_2, we also have n ∈ P_2. We moreover have p_2 ⊆ p_1 and hence \llbracket com\rrbracket(p_2) ⊆ \llbracket com\rrbracket(p_1). We conclude \llbracket com\rrbracket(p_2) ⊆ n as required.

2c. It remains to argue for safe_{P, i_2}^{k_2-1}(st', n, q_2). We have 0 < k_2 ≤ k_1 + 1. Hence, 0 ≤ k_2 - 1 ≤ k_1.

We have safe_{P, i_2}^{k_2-1}(st', n, q_1). The induction hypothesis yields safe_{P, i_2}^{k_2-1}(st', n, q_2). \square

Soundness of the thread-local derivation is stated in the next proposition.

**Proposition 45.** Consider P, I ⊨ \{ p \} st \{ q \} and k ∈ N. We have safe_{P, i}^k(st, p, q).

The proof of Proposition 45 proceeds by rule induction over the derivation rules of the program logic (Figure 5). We break the proof down into individual lemmas based on the case analysis of the last derivation rule used in the proof.

E.1 Soundness of seq

**Lemma 46.** If safe_{P, i_1}^k(st_1, p, q) and safe_{P, i_2}^k(st_2, q, o) and P = P_1 ∪ P_2 and I = I_1 ∪ I_2, then safe_{\{q\} ∪ P, I}^k(st_1; st_2, p, o).
We already noticed we can again pick \( n \).

We prove a fact that will be helpful.

\[(2c) \text{We have} \quad \text{safe}^{k+1}_{z_1; i_1} (st_1, p, q) \wedge \text{safe}^{k+1}_{z_2; i_2} (st_2, q, o) \implies \text{safe}^{k}_{\{q\} \cup \{p\}; i_1}(st_1; st_2, p, o) .\]

Consider \( st_1 \) and \( p \) so that

\[ \text{safe}^{k+1}_{z_1; i_1} (st_1, p, q) \wedge \text{safe}^{k+1}_{z_2; i_2} (st_2, q, o) . \]

Our goal is to show

\[ \text{safe}^{k+1}_{\{q\} \cup \{p\}; i_1}(st_1; st_2, p, o) . \]

(1) As \( st_1; st_2 \neq \text{skip} \), there is nothing to show.

(2) Consider \( \text{com} \) and \( st' \) with \( st_1; st_2 \xrightarrow{\text{con}} st' \).

There are two cases for transitions from \( st_1; st_2 \).

**Case 1:** \( st_1 = \text{skip} \) and \( \text{skip}; st_2 \xrightarrow{\text{skip}} st_2 \).

(2a) We have \( \neg \text{eff}(p, \text{skip}) \), hence \( \text{inter}(p, \text{skip}) = \emptyset \subseteq 1 \).

(2b) We argue that \( q \) is the right choice for a predicate. It is in \( \{q\} \cup \mathbb{P} \). We have \( \text{safe}^{k+1}_{z_1; i_1} (st_1, p, q) \) by assumption and \( st_1 = \text{skip} \). Hence, \( p \subseteq q \) holds. With this, \( \llbracket \text{skip} \rrbracket(p) = p \subseteq q \) follows.

(2c) By assumption, \( \text{safe}^{k+1}_{z_2; i_2} (st_2, q, o) \). Monotonicity in Lemma 44 then yields \( \text{safe}^{k}_{\{q\} \cup \{p\}; i_1}(st_1; st_2, q, o) . \)

**Case 2:** \( st_1 \xrightarrow{\text{con}} st'_1 \) and \( st_1; st_2 \xrightarrow{\text{con}} st'_1; st_2 \).

(2a) By the assumption of the induction step, we have the following: \( \text{safe}^{k+1}_{z_1; i_1} (st_1, p, q) \). Hence, \( \text{inter}(p, \text{com}) \subseteq 1 \subseteq 1 \).

(2b) Furthermore, there is some \( n \in \mathbb{P}_1 \) with \( \llbracket \text{com} \rrbracket(p) \subseteq n \) and \( \text{safe}^{k}_{z_1; i_1} (st'_1, n, q) \). Since \( 1 \subseteq \{p\} \cup \mathbb{P} \), we can again pick \( n \).

(2c) We have \( \text{safe}^{k+1}_{z_2; i_2} (st_2, q, o) \) by assumption. By monotonicity in Lemma 44, \( \text{safe}^{k}_{z_2; i_2}(st_2, q, o) \). We already noticed \( \text{safe}^{k}_{z_1; i_1}(st'_1, n, q) \). The induction hypothesis yields \( \text{safe}^{k}_{\{q\} \cup \{p\}; i_1}(st'_1; st_2, n, o) . \)

\[\square\]

### E.2 Soundness of \( \text{COM-SEM} \)

We prove a fact that will be helpful.

**Lemma 47.** \( \text{safe}^{k}_{\{p\}; \omega}(\text{skip}, p, p) \).

**Proof.** Consider \( p \). We proceed by induction on \( k \).

\( k = 0 \): Done.

\( k + 1 \): The induction hypothesis is

\[ \text{safe}^{k}_{\{p\}; \omega}(\text{skip}, p, p) . \]

Our goal is to prove

\[ \text{safe}^{k+1}_{\{p\}; \omega}(\text{skip}, p, p) . \]

(1) We have \( p \subseteq p \).

(2) The only transition is \( \text{skip} \xrightarrow{\text{skip}} \text{skip} \). As \( \neg \text{eff}(p, \text{skip}) \), we have \( \text{inter}(p, \text{skip}) = \emptyset \).

(2b) As predicate \( q \) we pick \( p \), which is in \( \{p\} \). Then \( \llbracket \text{skip} \rrbracket(p) = p \).

(2c) We have \( \text{safe}^{k+1}_{\mathbb{E}; \omega}(\text{skip}, p, p) \) by induction.

\[\square\]

Soundness of \( \text{COM-SEM} \) is formalized by the following lemma.
Lemma 48. \( P = \{ q \} \) and \( I = \text{inter}(p, \text{com}) \) and \( \llbracket \text{com} \rrbracket(p) \subseteq q \) imply \( \text{safe}_{P, I}^k(p, q) \).

Proof. We consider \( k + 1 \), for \( k = 0 \) there is nothing to do. We show

\[
\text{safe}_{P, I}^{k+1}(p, q).
\]

1. If \( \text{com} = \text{skip} \), we have \( p = \llbracket \text{com} \rrbracket(p) \). By the assumption, \( \llbracket \text{com} \rrbracket(p) \subseteq q \). Hence, \( p \subseteq q \) as required.

2. Consider \( \text{com} \xrightarrow{\text{con}} \text{skip} \).

2a. We have \( \text{inter}(p, \text{com}) = I \) by assumption.

2b. We pick \( n = q \), which is in \( P = \{ q \} \). Then \( \llbracket \text{com} \rrbracket(p) \subseteq q \) by the assumption.

2c. We have \( \{ q \} = P \). Then \( \text{safe}_{P, q}^k(\text{skip}, q, q) \) by Lemma 47. Monotonicity in Lemma 44 yields \( \text{safe}_{P, I}^k(\text{skip}, q, q) \).

\( \square \)

E.3 Soundness of choice

Lemma 49. If \( \text{safe}_{P_1, I_1}^k(st_1, p, q) \) and \( \text{safe}_{P_2, I_2}^k(st_2, p, q) \) and \( P = P_1 \cup P_2 \) and \( I = I_1 \cup I_2 \), then

\( \text{safe}_{P, I}^k(st_1 + st_2, p, q) \).

Proof. Consider \( st_1, st_2, \) and \( q \). We proceed by induction on \( k \).

1. \( k = 0 \): Done.

2. \( k + 1 \): The induction hypothesis is

\[
\forall p. \text{safe}_{P_1, I_1}^k(st_1, p, q) \land \text{safe}_{P_2, I_2}^k(st_2, p, q) \implies \text{safe}_{P, I}^k(st_1 + st_2, p, q).
\]

Consider \( p \) with

\[
\text{safe}_{P_1, I_1}^{k+1}(st_1, p, q) \land \text{safe}_{P_2, I_2}^{k+1}(st_2, p, q).
\]

Our goal is to show

\[
\text{safe}_{P, I}^{k+1}(st_1 + st_2, p, q).
\]

1. We have \( st_1 + st_2 \neq \text{skip} \), hence there is nothing to show.

2a. We have \( st_1 + st_2 \xrightarrow{\text{skip}} st_i \) with \( i = 1, 2 \). As \( \text{noteff}(p, \text{skip}) \), we have \( \text{inter}(p, \text{com}) = \emptyset \subseteq I \).

2b. As \( \text{safe}_{P_1, I_1}^{k+1}(st_i, p, q) \) by assumption, there is \( n \in P_1 \) as follows. We have \( \llbracket \text{com} \rrbracket(p) \subseteq n \) and

\[
\text{safe}_{P_1, I_1}^k(st_i, n, q).
\]

As \( P_1 \subseteq P \), we can again pick \( n \).

2c. Moreover, \( \text{safe}_{P_1, I_1}^k(st_i, n, q) \) implies \( \text{safe}_{P_1, I_1}^k(st_i, n, q) \) by monotonicity in Lemma 44.

\( \square \)

E.4 Soundness of infer-sem

Follows directly from monotonicity in Lemma 44.

E.5 Soundness of loop

We first prove some helpful auxiliary lemmas.

Lemma 50. If we have \( r \in P \) and \( \text{safe}_{P, I}^k(st; st^*, r, p) \) and \( \text{safe}_{P, I}^k(\text{skip}, r, p) \), then \( \text{safe}_{P, I}^{k+1}(st^*, r, p) \).

Proof. Consider \( st \) and \( p \). We proceed by induction on \( k \).

1. \( k = 0 \): Done.

2. \( k + 1 \): The induction hypothesis is:

\[
\forall r \in P. \text{safe}_{P_1, I_1}^k(st; st^*, r, p) \land \text{safe}_{P_2, I_2}^k(\text{skip}, r, p) \implies \text{safe}_{P_1, I_1}^{k+1}(st^*, r, p).
\]

Consider \( r \in P \) so that

\[
\text{safe}_{P_1, I_1}^{k+1}(st; st^*, r, p) \land \text{safe}_{P_2, I_2}^{k+1}(\text{skip}, r, p).
\]
We show \( \mathit{safe}_{P,I}^{k+2}(st^*, r, p) \).

(1) As \( st^* \neq \mathit{skip} \), there is nothing to show.

(2) The only transition is \( st^* \xrightarrow{\mathit{skip}} \mathit{skip} + st; st^* \).

(2a) As \( \neg \mathit{eff}(r, \mathit{skip}) \), we have \( \mathit{inter}(r, \mathit{com}) = \emptyset \) and hence \( \mathit{inter}(r, \mathit{com}) \subseteq I \).

(2b) As predicate \( n \) we choose \( r \), of which we know it is in \( P \). We have \( \llbracket \mathit{skip} \rrbracket(r) = r \).

(2c) By assumption, we have \( \mathit{safe}_{P,I}^{k+1}(st; st^*, r, p) \) as well as \( \mathit{safe}_{P,I}^{k+1}(\mathit{skip}, r, p) \). With Lemma 49, we get \( \mathit{safe}_{P,I}^{k+1}(\mathit{skip} + st; st^*, r, p) \).

This concludes the proof of \( \mathit{safe}_{P,I}^{k+2}(st^*, r, p) \). \( \square \)

**LEMMA 51.** If \( \mathit{safe}_{P,I}^{k}(st_1, r, p) \) and \( \mathit{safe}_{\{p\} \cup P,I}^{k}(st^*, p, p) \) hold, then \( \mathit{safe}_{\{p\} \cup P,I}^{k}(st_1; st^*, r, p) \).

**PROOF.** Consider \( st \) and \( p \). We proceed by induction on \( k \).

\( k = 0 \): There is nothing to do.

\( k + 1 \): The induction hypothesis is

\[
\forall st_1. \forall r. \mathit{safe}_{P,I}^{k}(st_1, r, p) \land \mathit{safe}_{\{p\} \cup P,I}^{k}(st^*, p, p) \implies \mathit{safe}_{\{p\} \cup P,I}^{k}(st_1; st^*, r, p).
\]

Consider \( st_1 \) and \( r \) so that

\[
\mathit{safe}_{P,I}^{k+1}(st_1, r, p) \land \mathit{safe}_{\{p\} \cup P,I}^{k+1}(st^*, p, p).
\]

We show

\[
\mathit{safe}_{\{p\} \cup P,I}^{k+1}(st_1; st^*, r, p).
\]

(1) As \( st_1; st^* \neq \mathit{skip} \), there is nothing to show.

(2) Consider \( st_1; st^* \xrightarrow{\mathit{con}} st' \). There are two cases for transitions from \( st_1; st^* \).

**Case 1:** We have \( st_1 = \mathit{skip} \) and \( st_1; st^* \xrightarrow{\mathit{skip}} st^* \).

(2a) Since \( \neg \mathit{eff}(r, \mathit{skip}) \), we have \( \mathit{inter}(r, \mathit{skip}) = \emptyset \subseteq I \).

(2b) We argue that \( p \) is the right predicate to pick as \( n \). It is in \( \{p\} \cup P \). We have \( \llbracket \mathit{skip} \rrbracket(r) = r \). By \( \mathit{safe}_{P,I}^{k+1}(st_1, r, p) = \mathit{safe}_{P,I}^{k+1}(\mathit{skip}, r, p) \), we have \( r \subseteq p \). Hence, \( \llbracket \mathit{skip} \rrbracket(r) \subseteq p \).

(2c) By assumption, \( \mathit{safe}_{P,I}^{k+1}(st^*, p, p) \). By Lemma 44, we get the desired \( \mathit{safe}_{\{p\} \cup P,I}^{k}(st^*, p, p) \).

**Case 2:** We have \( st_1; st^* \xrightarrow{\mathit{con}} st' \) due to \( st_1 \xrightarrow{\mathit{con}} st_1' \) and \( st' = st_1'; st^* \).

(2a) Since \( \mathit{safe}_{P,I}^{k+1}(st_1, r, p) \), we have \( \mathit{inter}(r, \mathit{com}) \subseteq I \).

(2b) By the same assumption, there is some \( n \in P \) such that \( \mathit{com}(r) \subseteq n \) and \( \mathit{safe}_{P,I}^{k+1}(st_1', n, p) \).

(2c) Since \( \mathit{safe}_{\{p\} \cup P,I}^{k}(st^*, p, p) \), we have \( \mathit{safe}_{\{p\} \cup P,I}^{k}(st^*, p, p) \) with Lemma 44. We apply the induction hypothesis to \( \mathit{safe}_{P,I}^{k+1}(st_1', n, p) \) and \( \mathit{safe}_{\{p\} \cup P,I}^{k}(st^*, p, p) \). It yields \( \mathit{safe}_{\{p\} \cup P,I}^{k}(st_1; st^*, n, p) \).

This concludes the proof of \( \mathit{safe}_{\{p\} \cup P,I}^{k+1}(st_1; st^*, r, p) \). \( \square \)

**Soundness of LOOP** is the following.

**LEMMA 52.** If \( \mathit{safe}_{P,I}^{k}(st, p, p) \), then \( \mathit{safe}_{\{p\} \cup P,I}^{k}(st^*, p, p) \).

**PROOF.** Consider \( P, I, p, \) and \( st \). We proceed by induction on \( k \).

\( k = 0 \): Done.

\( k + 1 \): The induction hypothesis is

\[
\mathit{safe}_{P,I}^{k}(st, p, p) \implies \mathit{safe}_{\{p\} \cup P,I}^{k}(st^*, p, p).
\]
We assume
\[ \text{safe}^{k+1}_{p,I}(st, p, p) \]
Our goal is to show
\[ \text{safe}^{k+1}_{\langle p \rangle \cup P,I}(st^*, p, p). \]
By assumption, we have \( \text{safe}^{k+1}_{p,I}(st, p, p) \). This yields \( \text{safe}^{k}_{p,I}(st, p, p) \) by Lemma 44. The induction hypothesis yields \( \text{safe}^{k}_{\langle p \rangle \cup P,I}(st^*, p, p) \). Lemma 51 yields \( \text{safe}^{k}_{\langle p \rangle \cup P,I}(st; st^*, p, p) \). Lemma 47 yields \( \text{safe}^{k}_{\langle p \rangle \cup \emptyset}(skip, p, p) \). Monotonicity in Lemma 44 yields \( \text{safe}^{k}_{\langle p \rangle \cup P,I}(skip, p, p) \). We can thus invoke Lemma 50. It yields the required \( \text{safe}^{k+1}_{\langle p \rangle \cup P,I}(st^*, p, p) \).

\[ \square \]

E.6 Soundness of FRAME

We first prove an auxiliary lemma stating that due to the locality of commands, effectfullness of commands is compatible with framing.

**Lemma 53.** \( \text{eff}(o * p, com) \) implies \( \text{eff}(o, com) \).

**Proof.** We prove the contrapositive:
\[ \neg \text{eff}(o, com) \implies \neg \text{eff}(o * p, com). \]
Consider some \( (g_1, l_1) \in o \) and some \( (g_2, l_2) \in p \) such that \( (g_1 * g_2, l_1 * l_2) = (g_1, l_1) * (g_2, l_2) \in o * p \).
By the locality of commands, we have
\[ \| \text{com} \|( (g_1, l_1) * (g_2, l_2)) \subseteq \| \text{com} \|(g_1, l_1) * \{ (g_2, l_2) \}. \]
Since \( \neg \text{eff}(o, com) \) and \( (g_1, l_1) \in o \), every state in \( \| \text{com} \|(g_1, l_1) \) takes the form \( (g_1, l) \) for some \( l \). Consequently, every state in \( \| \text{com} \|( (g_1, l_1) * (g_2, l_2)) \) must be of the following form: \( (g_1, l) * (g_2, l_2) = (g_1 * g_2, l_1 * l_2) \), and is thus as required.

Soundness of FRAME is this.

**Lemma 54.** If \( \text{safe}^{k}_{P,I}(st, r, q) \), then \( \text{safe}^{k}_{P * o * (r) + o}(st, r * o, q * o) \).

**Proof.** Consider \( q, I, P, \) and \( o \). We proceed by induction on \( k \).

- \( k = 0 \): There is nothing to do.
- \( k + 1 \): The induction hypothesis is
\[ \forall st. \forall r. \text{safe}^{k}_{P,I}(st, r, q) \implies \text{safe}^{k}_{P * o * (r) + o}(st, r * o, q * o). \]
Consider \( st \) and \( r \) with \( \text{safe}^{k+1}_{P,I}(st, r, q) \). We show
\[ \text{safe}^{k+1}_{P,I}(st, r * o, q * o). \]

1. Assume \( st = \text{skip} \), otherwise there is nothing to do. Since \( \text{safe}^{k+1}_{P,I}(st, r, q) \), we have \( r \subseteq q \). Hence, \( r * o \subseteq q * o \), as required.
2. Consider \( com \) and \( st' \) so that \( st \xrightarrow{com} st' \). By assumption, we have \( \text{safe}^{k+1}_{P,I}(st, r, q) \).
   a. If \( \text{inter}(r * o, com) = \emptyset \), then \( \text{inter}(r * o, com) \subseteq I * o \) follows trivially. So assume that we have \( \text{inter}(r * o, com) = \{(r * o, com)\} \). Then \( \text{eff}(r * o, com) \). By Lemma 53, we get \( \text{eff}(r, com) \). Hence, \( \text{inter}(r, com) = \{(r, com)\} \). Since \( \text{safe}^{k+1}_{P,I}(st, r, q) \), we have \( \text{inter}(r, com) \subseteq I \). This means there is \( (o', com) \in I \) with \( r \subseteq o' \). Then \( r * o \subseteq o' * o \). Moreover, \( (o' * o, com) \in I * o \), as required.
   b. Because of \( \text{safe}^{k+1}_{P,I}(st, r, q) \), there is \( n \in P \) with \( \| \text{com} \|(r) \subseteq n \) and \( \text{safe}^{k}_{P,I}(st', n, q) \). We have \( n * o \in P * o \). We argue that this is the right choice for a predicate. By \( \| \text{com} \|(r) \subseteq n \) and the locality
of commands, \( \llbracket \text{com} \rrbracket (r \ast o) \subseteq n \ast o \), as required.

(2c) We have \( \text{cfsafe}^k_{\pi, l}(\text{st}', n, q) \). Induction yields the desired \( \text{cfsafe}^k_{\pi, l}(\text{st}', n \ast o, q \ast o) \).

\( \square \)

### E.7 Interference-Freedom

Interference freedom lifts the safety guarantee from an isolated thread to the concurrency library.

**Definition 55.** We define \( \text{cfsafe}^0(\text{cf}, q) \triangleq \text{true} \) as well as \( \text{cfsafe}^{k+1}(\text{cf}, q) \triangleq (1) \land (2) \) with

1. \( \text{cf} \in \text{Acc}_q \)
2. \( \forall \text{cf}'. \; \text{cf} \rightarrow \text{cf}' \iff \text{cfsafe}^k(\text{cf}', q) \).

The key lemma for lifting the thread-local safety guarantee to configurations is the following.

**Lemma 56.** If \( \text{cf} = (g, pc) \) and \( \forall i. \forall l. \forall \text{st}. \text{pc}(i) = (l, \text{st}) \Rightarrow \exists r \in \mathbb{P}. \; (g, l) \in r \land \text{safe}^k_{\pi, l}(\text{st}, r, q) \), then \( \text{cfsafe}^k(\text{cf}, q) \).

**Proof.** Consider \( \mathbb{P} \) and \( \mathcal{I} \) with \( \pi, \mathcal{I} \mathbb{P} \). Consider \( q \). We proceed by induction on \( k \).

\( k = 0 \): Done.

\( k + 1 \): The induction hypothesis is

\[
\forall g, \forall \text{pc}. \; \left( \forall i. \forall l. \forall \text{st}. \text{pc}(i) = (l, \text{st}) \Rightarrow \exists r \in \mathbb{P}. \; (g, l) \in r \land \text{safe}^k_{\pi, l}(\text{st}, r, q) \right) \\
\Rightarrow \text{cfsafe}^k((g, \text{pc}), q).
\]

Consider \( \text{cf} = (g, pc) \) so that for all \( i, l, \text{st} \) we have

\[
\text{pc}(i) = (l, \text{st}) \Rightarrow \exists r \in \mathbb{P}. \; (g, l) \in r \land \text{safe}^{k+1}_{\pi, l}(\text{st}, r, q).
\]

We show \( \text{cfsafe}^{k+1}(\text{cf}, q) \).

1. To show \( \text{cf} \in \text{Acc}_q \), let thread \( i \) be with \( \text{pc}(i) = (l, \text{skip}) \). By assumption, there is a predicate \( r \in \mathbb{P} \) so that \( (g, l) \in r \) and \( \text{safe}^{k+1}_\pi(\text{skip}, r, q) \). By definition of \( \text{safe}^{k+1}_\pi(\text{skip}, r, q) \), we have \( r \subseteq q \).

   Hence, \( (g, l) \in q \), as required.

2. Consider a configuration \( \text{cf}' \) with \( \text{cf} \rightarrow \text{cf}' = (g', pc') \). To establish \( \text{cfsafe}^k(\text{cf}', q) \), let thread \( i \) be with \( \text{pc}(i) = (l, \text{st}) \) and \( \text{pc}'(i) = (l', \text{st}') \). We show that there is a predicate \( n \in \mathbb{P} \) with \( (g', l') \in n \) and \( \text{safe}^k_{\pi, l}(\text{st}', n, q) \). The induction hypothesis then yields \( \text{cfsafe}^k(\text{cf}', q) \) and concludes the proof. There are two cases.

   **Case 1:** Thread \( i \) executes the command \( \text{st} \xrightarrow{\text{con}} \text{st}' \) that leads to the transition \( \text{cf} \rightarrow \text{cf}' \). Then \( (g', l') \in \llbracket \text{con} \rrbracket (g, l) \). By assumption, there is a predicate \( r \in \mathbb{P} \) so that \( (g, l) \in r \) and \( \text{safe}^{k+1}_\pi(\text{st}, r, q) \).

   The definition of safety gives some \( n \in \mathbb{P} \) with \( \llbracket \text{con} \rrbracket (r) \subseteq n \). Then \( (g', l') \in \llbracket \text{con} \rrbracket (g, l), (g, l) \in r \), and \( \llbracket \text{con} \rrbracket (r) \subseteq n \) together entail \( (g', l') \in n \). Moreover, the predicate \( n \) satisfies \( \text{safe}^k_{\pi, l}(\text{st}', n, q) \), as required. In the second case, we use that safety of the executing thread also yields \( \text{inter}(r, \text{con}) \subseteq \mathcal{I} \).

   Hence, if \( \text{eff}(r, \text{con}) \), then there is \( (a, \text{com}) \in \mathcal{I} \) with \( r \subseteq a \).

   **Case 2:** Thread \( i \) experiences the command as an interference. Hence, \( \text{pc}'(i) = \text{pc}(i) = (l, \text{st}) \) but potentially \( g' \neq g \). By assumption, there is a predicate \( r \in \mathbb{P} \) so that \( (g, l) \in r \) and \( \text{safe}^{k+1}_\pi(\text{st}, r, q) \).

   We show that \( n = r \) is the right choice. We already argued that the interference is covered by some \( (a, \text{com}) \in \mathcal{I} \). Hence, we have \( (g', l) \in \llbracket (a, \text{com}) \rrbracket (g, l) \). Moreover \( \llbracket (a, \text{com}) \rrbracket (g, l) \leq \llbracket (a, \text{com}) \rrbracket (r) \).

   By interference freedom, we have \( \llbracket (a, \text{com}) \rrbracket (r) \subseteq r \). Hence, \( (g', l) \in r \). Moreover, \( \text{safe}^{k+1}_\pi(\text{st}, r, q) \) entails the desired \( \text{safe}^k_{\pi, l}(\text{st}, r, q) \) by Lemma 44. 

\( \square \)

### E.8 Soundness

Finally, we can prove the overall soundness theorem.
Proof of Theorem 3. Assume $\mathcal{P}, \mathcal{I} \models \{ p \} \cup \{ q \}$ and $\mathcal{P} \not\models p \in \mathcal{P}$. In order to show that $\models \{ p \} \cup \{ q \}$ holds, consider a configuration $(g, pc) \in \text{Init}_{\mathcal{P}, \mathcal{I}}$. By definition of $\text{Init}_{\mathcal{P}, \mathcal{I}}$, every thread $i$ satisfies $pc(i) = (l, st)$ with $(g, l) \in p$. By $\mathcal{P}, \mathcal{I} \models \{ p \} \cup \{ q \}$ and Proposition 45, we have $\text{safe}^k_{\mathcal{P}, \mathcal{I}}(st, p, q)$ for every $k$. With $\mathcal{P}, p \in \mathcal{P}$, and Lemma 56, we get $\text{csafe}^k((g, pc), q)$ for all $k$. This shows that every reachable configuration is accepting for $q$. \hfill $\Box$

F PROOFS OF SECTION 6

We will first prove an auxiliary lemma, which we will use to show the soundness of $\text{F-INFER}$.

Lemma 57. $p_2 \subseteq p_1$ and $q_1 \subseteq q_2$ imply $p_1 \Rightarrow q_1 \subseteq p_2 \Rightarrow q_2$.

Proof. Consider $s \in p_1 \Rightarrow q_1$. Then $\{ s \} * p_1 \subseteq q_1$. As $p_2 \subseteq p_1$, we get $\{ s \} * p_2 \subseteq q_1$. As $q_1 \subseteq q_2$, we get $\{ s \} * p_2 \subseteq q_2$. This means $s \in p_2 \Rightarrow q_2$. \hfill $\Box$

Proof of Lemma 6. We prove validity of each of the rules in succession.

(i) Soundness of $\text{F-INTRO}$. We have $\text{emp} * p = p$. Moreover, we have:

$$\langle p \rangle \text{ com } \langle q \rangle = p \Rightarrow \text{wp}(\text{com}, q) = \{ s \mid \{ s \} * p \subseteq \text{wp}(\text{com}, q) \}$$

We thus have to show $\text{emp} * p = p \subseteq \text{wp}(\text{com}, q)$. This holds by assumption.

(ii) Soundness of $\text{F-SEQ}$. Consider $s \in \langle p \rangle \text{ com } \langle q \rangle * \langle q \rangle \text{ com } \langle o \rangle$. Then we have $s = s_1 * s_2$ with $s_1 \in \langle p \rangle \text{ com } \langle q \rangle$ and $s_2 \in \langle q \rangle \text{ com } \langle o \rangle$. So we arrive at $\{ s \} * p = \{ s_2 \} * (\{ s_1 \} * p)$. Then, by the locality of commands, we obtain $\text{com}_1(\{ s \} * p) \subseteq \{ s_2 \} * \text{com}_1(\{ s_1 \} * p)$. As $s_1 \in \langle p \rangle \text{ com } \langle q \rangle$, we have $\text{com}_1(\{ s_1 \} * p) \subseteq q$. Hence, we get $\text{com}_1(\{ s \} * p) \subseteq \{ s_2 \} * q$. This means we arrive at $\{ s \} * p \subseteq \text{wp}(\text{com}_1, \{ s_2 \} * q)$. As $s_2 \in \langle q \rangle \text{ com } \langle o \rangle$, we have $\{ s_2 \} * q \subseteq \text{wp}(\text{com}_2, o)$. Together:

$$\{ s \} * p \subseteq \text{wp}(\text{com}_1, \{ s_2 \} * q) \subseteq \text{wp}(\text{com}_1, \text{wp}(\text{com}_2, o)) = \text{wp}(\text{com}_1; \text{com}_2, o)$$

By assumption, $\text{wp}(\text{com}_1; \text{com}_2, o) \subseteq \text{wp}(\text{com}, o)$. Hence, we arrive at $\{ s \} * p \subseteq \text{wp}(\text{com}, o)$. This shows $s \in \langle p \rangle \text{ com } \langle o \rangle$, as required.

(iii) Soundness of $\text{F-ACCOUNT}$. Consider $s \in p * \langle p \Rightarrow q \rangle \text{ com } \langle o \rangle$. Then $s = s_1 * s_2$ with $s_1 \in p$ and $s_2 \in \langle p \Rightarrow q \rangle \text{ com } \langle o \rangle$. The latter means $\text{com}_1(\{ s_2 \} * p * q) \subseteq o$. As $s_1 \in p$, we in particular have $\text{com}_1(\{ s_2 \} * s_1) \subseteq o$. Since $\text{com}_1(\{ s_2 \} * s_1) = \text{com}_1(\{ s \} * q)$, we obtain the required $s \in \langle q \rangle \text{ com } \langle o \rangle$.

(iv) Soundness of $\text{F-INFER}$. If $q_1 \subseteq q_2$, then $\text{wp}(\text{com}, q_1) \subseteq \text{wp}(\text{com}, q_2)$. We conclude as follows:

$$\langle p_1 \rangle \text{ com } \langle q_1 \rangle$$

( Definition 5 ) $= p_1 \Rightarrow \text{wp}(\text{com}, q_1)$

( Lemma 57 and assumption ) $\subseteq p_2 \Rightarrow \text{wp}(\text{com}, q_1)$

( Lemma 57 and remark above ) $\subseteq p_2 \Rightarrow \text{wp}(\text{com}, q_2)$

( Definition 5 ) $= \langle p_2 \rangle \text{ com } \langle q_2 \rangle$.

(v) Soundness of $\text{F-FRAME}$. Consider $s \in \langle p \rangle \text{ com } \langle q \rangle$. Then $\{ s \} * p \subseteq \text{wp}(\text{com}, q)$. This in turn means $\text{com}_1(\{ s \} * p) \subseteq q$. By the locality of commands, we have $\text{com}_1(\{ s \} * p * o) \subseteq q * o$. This means $\{ s \} * p * o \subseteq \text{wp}(\text{com}, q * o)$. Hence, $s \in \langle p * o \rangle \text{ com } \langle q * o \rangle$. 

Roland Meyer, Thomas Wies, and Sebastian Wolff
(vi) **Soundness of $P$-INVOKE.** We conclude by:

\[
p * (p) \text{ com } q \\
(\text{emp neutral}) = p * (p * \text{ emp}) \text{ com } q \\
(\text{Soundness of } P\text{-ACCOUNT}) \subseteq \text{ emp com } q \\
(\text{Definition 5}) = \text{ emp wp(com, q)} \\
(\text{emp neutral}) = \text{ wp(com, q)}. \\
\]

\[\square\]

**G PROOFS OF SECTION 7**

**Proof of Lemma 10.** Consider $\sigma' \in \llbracket \text{ com} \rrbracket (a * c)$. Then there is $\sigma \in a * c$ with $\sigma' \in \llbracket \text{ com} \rrbracket (\sigma)$. Then $\sigma = \sigma_1.s_1 * \sigma_2.s_2$ with $\sigma_1.s_1 \in a$ and $\sigma_2.s_2 \in c$. By definition, $\sigma' = \sigma.s'$ with $s' \in \llbracket \text{ com} \rrbracket (s_1.s_2)$. By locality of commands, $\llbracket \text{ com} \rrbracket (s_1.s_2) \subseteq \llbracket \text{ com} \rrbracket (s_1) * \llbracket \text{ com} \rrbracket (s_2)$. Hence, $s' = s'_1.s_2$ with $s'_1 \in \llbracket \text{ com} \rrbracket (s_1)$. By definition, $\sigma_1.s_1.s'_1 \in \llbracket \text{ com} \rrbracket (\sigma_1.s_1)$. Since $\sigma_1.s_1 \in a$, we have $\sigma_1.s_1.s'_1 \in \llbracket \text{ com} \rrbracket (a)$. By frameability, we have $\sigma_2.s_2.s_2 \in c$. Hence, $\sigma_1.s_1.s'_1 * \sigma_2.s_2.s_2 \in \llbracket \text{ com} \rrbracket (a) * c$. Altogether, we arrive at $\sigma_1.s_1.s'_1 * \sigma_2.s_2.s_2 = \sigma.(s'_1.s_2) = \sigma'$. \[\square\]

We adapt the semantics of concurrency libraries to track history and show that the thread-modular reasoning principle remains sound. The first step is to lift the product separation algebra to a history separation algebra containing sequences from $(\Sigma_C \times \Sigma_L)^\times$. In a configuration of the concurrency library, we store the two components of such a sequence separately. So we store $(g_1, l_1) \ldots (g_n, l_n)$ as the pair $(y, \lambda)$ with $y = g_1 \ldots g_n$ and $\lambda = l_1 \ldots l_n$. Note that a predicate $a \subseteq (\Sigma_C \times \Sigma_L)^\times$ only contains pairs of sequences of the same length. A configuration of the concurrency library has the shape $(y, pc)$ with $y \in \Sigma_C^+$ a sequence of global states and for all threads $pc(i) = (\lambda, st)$ with $\lambda \in \Sigma_L^*$ an equally long sequence of local states. When we execute a transition, we not only update the local state of the thread being active. We also store a copy of the current local state in all other threads. This ensures the resulting sequences of global and local states are again of the same length. The modified transition relation is this.

\[
p_{c_1}(i) = (\lambda_1, st_1) \quad st_1 \xrightarrow{\text{com}} st_2 \quad (y_2, \lambda_2) \in \llbracket \text{ com} \rrbracket (y_1, \lambda_1) \quad pc_{c_2}(i) = (\lambda_2, st_2) \\
\forall j \neq i. \quad pc_{c_1}(j) = (\lambda_j, st_j) \quad pc_{c_2}(j) = (\lambda_j, \text{ last}(\lambda_j), st_j) \\
(y_1, pc_{c_1}) \rightarrow (y_2, pc_{c_2})
\]

We also adapt interference to copy the last local state:

\[
\llbracket (o, \text{ com}) \rrbracket (y, \lambda) \triangleq \{ (y', \lambda, \text{ last}(\lambda)) \mid \exists \lambda_1, \lambda_2. \ (y, \lambda_1) \in o \land (y', \lambda_2) \in \llbracket \text{ com} \rrbracket (y, \lambda_1) \}.
\]

Proposition 45 refers to a general separation algebra and therefore continues to hold in the present setting modulo the restriction of the **frame** rule to frameable predicates.

We now show that the key lemma for lifting the thread-local safety guarantee to configurations carries over to history separation algebras.

**Lemma 58.** If $\text{ cf } = (y, \text{ pc})$ and $[\forall i. \forall \lambda. \forall \text{ st. } pc(i) = (\lambda, \text{ st}). \Rightarrow \exists d \in \mathbb{P}. \ (y, \lambda) \in d \land \text{ safe}^{k}_{\text{ z1}}(\text{ st, d}, b)]$ and $\mathbb{F} \mathbb{P}$ hold, then we have $\text{ cfsafe}^{k}(\text{ cf, b})$.

**Proof of Lemma 58.** Consider $\mathbb{P}$ and $\mathbb{I}$ with $\mathbb{F} \mathbb{P}$. Consider $b$. We proceed by induction on $k$. $k = 0$: Done.
$k + 1$: The induction hypothesis is
\[ \forall \gamma \forall \mathbf{pc}. \left( \forall i. \forall \lambda. \forall \mathbf{st}. \ pc(i) = (\lambda, \mathbf{st}) \Rightarrow \exists d \in \mathbb{P}. (\gamma, \lambda) \in d \land \text{safe}^k_{\mathbb{P}, \mathbb{I}}(\mathbf{st}, d, b) \right) \]
\[ \Rightarrow \text{csafe}^k((\gamma, \mathbf{pc}), b). \]
Consider $\mathbf{cf} = (\gamma, \mathbf{pc})$ so that for all $i, \lambda, \mathbf{st}$ we have
\[ pc(i) = (\lambda, \mathbf{st}) \Rightarrow \exists d \in \mathbb{P}. (\gamma, \lambda) \in d \land \text{safe}^{k+1}_{\mathbb{P}, \mathbb{I}}(\mathbf{st}, d, b). \]
We show $\text{csafe}^{k+1}(\mathbf{cf}, b)$.

1. To show $\mathbf{cf} \in \text{Acc}_b$, let thread $i$ be with $pc(i) = (\lambda, \text{skip})$. By assumption, there is a predicate $d \in \mathbb{P}$ so that $(\gamma, \lambda) \in d$ and $\text{safe}^{k+1}_{\mathbb{P}, \mathbb{I}}(\text{skip}, d, b)$. By definition of $\text{safe}^{k+1}_{\mathbb{P}, \mathbb{I}}(\text{skip}, d, b)$, we have $d \subseteq b$. Hence, $\gamma(\lambda) = b$, as required.

2. Consider a configuration $\mathbf{cf}'$ with $\mathbf{cf} \rightarrow \mathbf{cf}' = (\gamma', \mathbf{pc}')$. We establish $\text{csafe}^k(\mathbf{cf}', b)$. Consider a thread $i$ with $pc(i) = (\lambda, \mathbf{st})$ and $pc'(i) = (\lambda', \mathbf{st}')$. We show that there is a predicate $e \in \mathbb{P}$ with $\gamma(\lambda') \in e$ and $\text{safe}^k_{\mathbb{P}, \mathbb{I}}(\mathbf{st}', e, b)$. The induction hypothesis then yields $\text{csafe}^k(\mathbf{cf}', b)$ and concludes the proof. There are two cases.

**Case 1:** Thread $i$ executes the command $\mathbf{st} \rightarrow \mathbf{st}'$ that leads to the transition $\mathbf{cf} \rightarrow \mathbf{cf}'$. Then $(\gamma', \lambda') \in \mathbb{com}\{\mathbf{st}, \mathbf{st}'\}(\gamma, \lambda)$. By assumption, there is a predicate $d \in \mathbb{P}$ with $(\gamma, \lambda) \in d$ and $\text{safe}^{k+1}_{\mathbb{P}, \mathbb{I}}(\mathbf{st}, d, b)$. The definition of safety gives a predicate $e \in \mathbb{P}$ with $\mathbb{com}\{\mathbf{st}, \mathbf{st}'\}(d) \subseteq e$. Then $(\gamma', \lambda') \in \mathbb{com}\{\mathbf{st}, \mathbf{st}'\}(\gamma, \lambda)$, $(\gamma, \lambda) \in d$, and $\mathbb{com}\{\mathbf{st}, \mathbf{st}'\}(d) \subseteq e$ together entail $(\gamma', \lambda') \in e$. Moreover, the predicate $e$ satisfies $\text{safe}^k_{\mathbb{P}, \mathbb{I}}(\mathbf{st}', e, b)$, as required. In the second case, we will use that safety of the executing thread also yields $\text{inter}((d, \text{com}), b) \subseteq b$. Hence, if $\text{eff}(d, \text{com})$, then there is $(c, \text{com}) \in b$ with $d \subseteq c$.

**Case 2:** Thread $i$ experiences the command as an interference. Then we have $pc(i) = (\lambda, \mathbf{st})$ and $pc'(i) = (\lambda, \text{last}(\lambda), \mathbf{st})$. By assumption, there is a predicate $d \in \mathbb{P}$ so that $(\gamma, \lambda) \in d$ and $\text{safe}^{k+1}_{\mathbb{P}, \mathbb{I}}(\mathbf{st}, d, b)$. We show that $e = d$ is the right choice. We already argued that the interference is covered by some $(c, \text{com}) \in b$. Hence, we have $(\gamma', \lambda, \text{last}(\lambda)) \in \mathbb{com}\{(c, \text{com})\}(\gamma, \lambda)$. Moreover, $\mathbb{com}\{(c, \text{com})\}(\gamma, \lambda) \subseteq \mathbb{com}\{(c, \text{com})\}(d)$. By interference freedom, we have $\mathbb{com}\{(c, \text{com})\}(d) \subseteq d$. Hence, $(\gamma', \lambda, \text{last}(\lambda)) \in d$. Moreover, $\text{safe}^{k+1}_{\mathbb{P}, \mathbb{I}}(\mathbf{st}, d, b)$ entails $\text{safe}^k_{\mathbb{P}, \mathbb{I}}(\mathbf{st}, d, b)$ by Lemma 44. □

The proof of Theorem 11 is the same as the one for Theorem 3, except that we replace Lemma 56 by the above Lemma 58.

**Proof of Theorem 11.** Assume that $\mathbb{P}, \mathbb{I} \not\models \{a\} \mathbf{st} \{b\}$ and $\mathbb{I} \models \mathbb{P}$ and $a \in \mathbb{P}$ hold. To show $\models \{a\} \mathbf{st} \{b\}$, consider a configuration $(\gamma, \mathbf{pc}) \in \text{Init}_{\mathbb{I}}$. By definition of $\text{Init}_{\mathbb{I}}$, every thread $i$ satisfies $pc(i) = (\lambda, \mathbf{st})$ with $(\gamma, \lambda) \in a$. By $\mathbb{P}, \mathbb{I} \not\models \{a\} \mathbf{st} \{b\}$ together with Proposition 45, we have $\text{safe}^k_{\mathbb{P}, \mathbb{I}}(\mathbf{st}, a, b)$ for every $k$. With $\mathbb{I} \models \mathbb{P}$, and Lemma 58, we get $\text{csafe}^k((\gamma, \mathbf{pc}), b)$ for all $k$. This shows that every reachable configuration is accepting for $b$. □

**Proof of Lemma 13.** (1) Let $\sigma.s \in \_p$, which means $s \in p$. Then also for $\sigma.s.s$ the last state belongs to $p$. Thus, $\sigma.s.s \in \_p$.
Consider $\sigma.s \in \diamond p$. This means there is a state from $p$ in $\sigma.s$. That state is still present in $\sigma.s.s$. Hence $\sigma.s.s \in \diamond p$, as required.

(2) Consider $\sigma.s \in a \ast b$. This means $\sigma.s = \sigma_1.s_1 \ast \sigma_2.s_2$ with $\sigma_1.s_1 \in a$ and $\sigma_2.s_2 \in b$. As $a$ and $b$ are frameable, we have $\sigma_1.s_1.s_1 \in a$ and $\sigma_2.s_2.s_2 \in b$. Hence, we obtain $\sigma.s.s = \sigma_1.s_1.s_1 \ast \sigma_2.s_2.s_2 \in a \ast b$.
Consider $\sigma.s \in a \cap b$. Since $a$ is frameable, we have $\sigma.s.s \in a$. With the same argument, $\sigma.s.s \in b$.
Hence, $\sigma.s.s \in a \cap b$.
The proof for union is the same. □
Proof of Lemma 14. We proceed by case analysis.

Case \( \Rightarrow \): "\( \subseteq \)" Let \( \sigma.s \in _{(p \rightarrow q)} \). To show \( \sigma.s \in _{(p \rightarrow q)} \), consider a computation \( \tau.t \in _{p} \) with \( \sigma.s \# \tau.t \). Note that definedness of the multiplication guarantees this shape. We have to show \( \sigma.s \cdot \tau.t = (\sigma \cdot \tau), (s \cdot t) \in _{q} \). Since \( \sigma.s \in _{(p \rightarrow q)} \), we have \( s \in p \rightarrow q \). Since \( \tau.t \in _{p} \), we have \( t \in p \). Hence, \( s \cdot t \in q \). This yields \( (\sigma \cdot \tau), (s \cdot t) \in _{q} \).

"\( \supseteq \)" Let \( \sigma.s \in _{(p \rightarrow q)} \). To show \( \sigma.s \in _{(p \rightarrow q)} \), we have to show \( s \in p \rightarrow q \). Consider \( t \in p \) with \( t \# \). Let \( 1_{\sigma} \) be the unique computation in \( \text{emp}^{[\sigma]} \) such that \( 1_{\sigma} \# \sigma \). The computation \( 1_{\sigma}, t \) is in \( _{p} \). Moreover, since \( 1_{\sigma} \# \sigma \) and \( t \# s \), we have \( 1_{\sigma}, t \# \sigma.s \). Hence, by the assumption, \( 1_{\sigma}, t \cdot \sigma.s = (\sigma \cdot t \cdot s) \in _{q} \). This shows \( t \cdot s \in q \) as required.

Case \( \Leftarrow \): "\( \subseteq \)" Consider \( \sigma.s \in _{(p \rightarrow q)} \). Then \( s \in p \rightarrow q \). This means \( s = s_{1} \cdot s_{2} \) with \( s_{1} \in p \) and \( s_{2} \in q \). Let \( 1_{\sigma} \) be the unique computation in \( \text{emp}^{[\sigma]} \) such that \( 1_{\sigma} \# \sigma \). Then \( \sigma.s_{1} \in _{p} \) and \( 1_{\sigma}, s_{2} \in _{q} \). Moreover, \( \sigma.s_{1} \# 1_{\sigma}, s_{2} = \sigma.s \in _{(p \rightarrow q)} \).

"\( \supseteq \)" Consider \( \sigma.s \in _{p \cdot q} \). By definition, there are \( \sigma.s_{1} \in _{p} \) as well as \( \sigma.s_{2} \in _{q} \) such that \( \sigma.s_{1} \cdot \sigma.s_{2} = \sigma.s \). We have \( s_{1} \in p \) and \( s_{2} \in q \). Hence, \( s \in p \cdot q \). Hence, \( \sigma.s \in _{(p \cdot q)} \).

Case \( \cap \): Consider \( \sigma.s \in _{(p \cap q)} \). We get \( s \in p \cdot q \), which means \( s \in p \) and \( s \in q \). Then \( \sigma.s \in _{(p \cap q)} \) and \( \sigma.s \in _{(p \cdot q)} \). This means \( s \in _{p \cap q} \).

Case \( \cup \): Consider \( \sigma.s \). We have \( \sigma.s \in _{(p \cup q)} \) iff \( s \in p \cup q \) iff \( s \notin p \) iff \( s \notin q \) iff \( s \in _{(p \cup q)} \).

Case false: We have \( \text{false} = \emptyset = \Sigma^{*} . \emptyset = _{(\emptyset)} \).

Case true: We have \( \text{true} = \Sigma^{+} = \Sigma^{*} . \Sigma = _{(\Sigma)} \).

Case inclusion: "\( \Rightarrow \)" Assume \( _{p} \subseteq _{q} \). Let \( s \in p \) be some state. The state is also a computation in \( _{q} \). As \( _{p} \subseteq _{q} \), we have \( s \in _{q} \), which means \( s \in q \).

"\( \Leftarrow \)" Assume \( p \subseteq q \). Consider a computation \( \sigma.s \in _{p} \). Then we have \( s \in p \), and hence \( s \in q \). Hence, \( \sigma.s \in _{q} \). \( \square \)

Proof of Lemma 15. We proceed by case analysis.

Case \( _{(p \cdot q)} \subseteq _{p} \): We have \( _{(p \cdot q)} = \Sigma^{*} . p \subseteq _{p} . \Sigma^{*} = _{p} \).

Case \( _{(p \cdot q)} \subseteq _{(p \cdot q)} \): Consider \( \sigma \in _{(p \cdot q)} \). Then there is a decomposition \( \sigma.s_{1} \cdot \sigma.s_{2} \) with \( s \in p \cdot q \). Then we have \( s = s_{1} \cdot s_{2} \) with \( s_{1} \in p \) and \( s_{2} \in q \). We define \( t_{1} = \sigma.s_{1} \cdot \sigma.s_{2} \in _{p} \). Let \( 1_{\sigma} \) be the unique computation in \( \text{emp}^{[\sigma]} \) such that \( 1_{\sigma} \# \sigma_{1} \) and define \( 1_{\sigma} \) similarly for \( \sigma_{2} \). We set \( t_{2} = 1_{\sigma_{1}} \cdot 1_{\sigma_{2}} \in _{q} \). Then \( \sigma = r_{1} \cdot r_{2} \in _{(p \cdot q)} \).

Case \( _{(p \cdot q)} \subseteq _{(p \cdot q)} \): Consider \( \sigma \in _{(p \cdot q)} \). Towards a contradiction, assume \( \sigma \notin _{(p \cdot q)} \). Then for every decomposition \( \sigma = \sigma_{1} . s_{2} \) we have \( s \notin p \cdot q \). This means there is \( t_{0} \in p \) with \( t_{0} \# s \) but \( s \cdot t_{0} \notin q \). Let \( r \) be the computation consisting of all such \( t_{0} \) (in the right order). Then \( \tau \in _{(p \cdot q)} \) and \( \tau \# \sigma \). Hence, \( \tau \# \sigma \in _{(p \cdot q)} \), because \( \sigma \in _{(p \cdot q)} \in _{(p \cdot q)} \). This, however, contradicts the construction of \( \tau \).

Case \( _{(p \cdot q)} \subseteq _{(p \cdot q)} \): We have \( p \cdot q \subseteq p \) and \( p \cdot q \subseteq q \). Hence, \( _{(p \cdot q)} \subseteq _{(p \cdot q)} \) and \( _{(p \cdot q)} \subseteq _{(p \cdot q)} \) by the equivalence for inclusion. Hence, \( _{(p \cdot q)} \subseteq _{(p \cdot q)} \).
Case $\diamond (p \cup q) = \diamond p \cup \diamond q$: “$\subseteq$” Consider $\sigma \in \diamond (p \cup q)$. Then $\sigma = \sigma_1.s.\sigma_2$ with $s \in p \cup q$, say $s \in p$. Then $\sigma = \sigma_1.s.\sigma_2 \in \diamond p$. 

“$\supseteq$” We get $\diamond (p \cup q) \supseteq \diamond p$ from $p \subseteq p \cup q$ and the equivalence for inclusion.

Case $true \ast \diamond p = \diamond (p \ast true)$: “$\subseteq$” Consider $\tau \ast \sigma \in true \ast \diamond p$. Then, $\tau = r_1.t.r_2$ and $\sigma = \sigma_1.s.\sigma_2$ with $|r_1| = |\sigma_1|$, $|r_2| = |\sigma_2|$, and $s \in p$. Consequently, we have $t \ast s \in true \ast p$. Hence, we arrive at $\tau \ast \sigma = (r_1 \ast \sigma_1).((t \ast s).r_2 \ast \sigma_2) \in \diamond (true \ast p)$.

“$\supseteq$” Consider $\sigma \in \diamond (p \ast true)$. Then, $\sigma = \sigma_1.s.\sigma_2$ with $s \in p \ast true$. Then, we get $s = s_1 \ast s_2$ with $s_1 \in p$. Then, $\sigma_1.s_1.\sigma_2 \in \diamond p$. Let $1_{\sigma_1}$ be the unique computation in $exp[|\sigma_1|]$ such that $1_{\sigma_1} \neq \sigma_1$ and define $1_{\sigma_2}$ similarly for $\sigma_2$. Then $1_{\sigma_1}.s_2.1_{\sigma_2} \in true$ is such that $\sigma_1.s_1.\sigma_2 \neq 1_{\sigma_1}.s_2.1_{\sigma_2}$. We have $\sigma_1.s_1.\sigma_2 \ast 1_{\sigma_1.s_2}.1_{\sigma_2} = \sigma \in \diamond p \ast true$.

The remaining cases are similar to the proof of Lemma 14.

PROOF OF LEMMA 16. Now: “$\subseteq$” Consider some $\sigma.s_1 \in wp(com, \_p)$, which means that we have $\llbracket com \rrbracket (\sigma.s_1) \subseteq \_p$. Hence, for all $\sigma.s_1.s_2 \in \llbracket com \rrbracket (\sigma.s_1)$ we have $s_2 \in \_p$. By definition, $s \in \llbracket com \rrbracket (s)$ implies $\sigma.s_1.s \in \llbracket com \rrbracket (\sigma.s_1)$. Hence, $\llbracket com \rrbracket (s) \subseteq \_p$, which means $\sigma.s_1 \in wp(com, \_p)$.

“$\supseteq$” For the reverse inclusion, consider $\sigma.s_1 \in \_wp(com, \_p)$. Then $s_1 \in wp(com, \_p)$, which means $\llbracket com \rrbracket (s) \subseteq \_p$. Consider a computation $\sigma.s_1.s_2 \in \llbracket com \rrbracket (\sigma.s_1)$. By definition, $s_2 \in \llbracket com \rrbracket (s)$. Since $\llbracket com \rrbracket (s) \subseteq \_p$, we get $\sigma.s_1.s_2 \in \_p$. This shows $\llbracket com \rrbracket (\sigma.s_1) \subseteq \_p$, which means $\sigma.s_1 \in \_wp(com, \_p)$.

Past: “$\subseteq$” Consider $\sigma.s_1 \in wp(com, \diamond p)$, which means that we have $\llbracket com \rrbracket (\sigma.s_1) \subseteq \diamond p$. Hence, for all $\sigma.s_1.s_2 \in \llbracket com \rrbracket (\sigma.s_1)$ we have $s_2 \in \diamond p$. There are two cases.

Case 1: A state from $\sigma.s_1$ belongs to $p$. Then $\sigma.s_1 \in \diamond p$.

Case 2: No state from $\sigma.s_1$ belongs to $p$. Then for all $\sigma.s_1.s_2 \in \llbracket com \rrbracket (\sigma.s_1)$ we have $s_2 \in \_p$. This means $\llbracket com \rrbracket (\sigma.s_1) \subseteq \_p$. Hence, $\sigma.s_1 \in wp(com, \_p)$.

“$\supseteq$” For the reverse inclusion, consider $\sigma.s_1 \in \diamond p$. Then for all $\sigma.s_1.s_2 \in \llbracket com \rrbracket (\sigma.s_1)$ we have $s_2 \in \diamond p$. Hence, $\sigma.s_1 \in wp(com, \diamond p)$.

Consider $\sigma.s_1 \in wp(com, \_p)$. Then for all $\sigma.s_1.s_2 \in \llbracket com \rrbracket (\sigma.s_1)$ we have $s_1.s_2 \in \_p$. Since $\_p \subseteq \diamond p$, we get $\sigma.s_1 \in wp(com, \diamond p)$.

PROOF OF LEMMA 18. Rule H-INTRO is trivial. Rule H-INFER is a consequence of Theorem 15. So, consider Rule H-HINDSIGHT. Let $(\sigma, i) \in \_p \ast \diamond q$. This means there are $(\sigma_1, i) \in \_p$ and $(\sigma_2, i) \in \diamond q$ so that $\sigma = \sigma_1 \ast \sigma_2$. Since $\_p$ is pure, we know that $\sigma_1 \in emp^\ast$. This yields $\sigma = \sigma_2$ and thus $(\sigma, i) \in \diamond q$. Again since $\_p$ is pure, we have $p \subseteq emp$. Hence, we obtain $q \subseteq p \ast q$ and thus $\diamond q \subseteq \diamond (p \ast q)$ by Theorem 15.

Recall that a predicate $i$ is intuitionistic, if $i \ast true = i$. Intuitionism propagates to the computation predicates, where true is defined to be the set of all computations.

LEMMA 59. If $i$ is an intuitionistic state predicate, then $\_i$ and $\diamond i$ are intuitionistic computation predicates.

PROOF OF LEMMA 59. Consider $\_i$. We have $\_i \ast true = \_i \ast \_true = \_i(i \ast true) = \_i$. The first two equalities are by Lemma 14, the last additionally uses the fact that $i$ is intuitionistic. The case of $\diamond i$ is similar.
H PROOFS OF SECTION C

Proof of Lemma 24. The laws of commutativity and units follow immediately from the definition of composition. For associativity we need to show that \( c_2 \# c_3 \) and \( c_1 \# (c_2 \ast c_3) \) if and only if \( c_1 \# c_2 \) and \( (c_1 \# c_2) \# c_3 \). We prove the direction from left to right. The reverse direction holds by symmetry of definedness.

Since \( c_2 \# c_3 \), we have \((c_2 \cup c_3).\text{flow} \geq c_2.\text{flow} \cup c_3.\text{flow}\). Furthermore, by \( c_1 \# (c_2 \ast c_3) \) we have

\[
(c_1 \cup (c_2 \ast c_3)).\text{flow} \geq c_1.\text{flow} \cup (c_2 \ast c_3).\text{flow} .
\]

Note that \((c_1 \cup (c_2 \ast c_3)).\text{flow} = (c_1 \cup c_2 \cup c_3).\text{flow}\).

To show \( c_1 \# c_2 \), we have to argue that

\[
(c_1 \cup c_2).\text{flow} \geq c_1.\text{flow} \cup c_2.\text{flow} .
\]

To see this, note that

\[
(c_1 \cup c_2).\text{flow} \geq (c_1 \cup c_2 \cup c_3).\text{flow}|_{(c_1 \cup c_2).X} \geq c_1.\text{flow} \cup c_2.\text{flow} .
\]

The latter inequality is by the assumptions. For the former inequality, we note that the fixed point iteration for \((c_1 \cup c_2).\text{flow}\) starts with a contribution from \(c_3\) (given as inflow) that the iteration for \((c_1 \cup c_2 \cup c_3).\text{flow}\) only receives when reaching the fixed point. By monotonicity, every fixed point approximant to the left is then larger than the corresponding approximant to the right, and so is the fixed point. For \((c_1 \ast c_2) \# c_3\), we note that

\[
((c_1 \ast c_2) \cup c_3).\text{flow} = (c_1 \cup c_2 \cup c_3).\text{flow} \geq c_1.\text{flow} \cup c_2.\text{flow} \cup c_3.\text{flow}
\]

\[
\geq (c_1 \cup c_2).\text{flow} \cup c_3.\text{flow} .
\]

The first inequality is by the above assumptions. The second always holds, as remarked above. \(\square\)

Proof of Lemma 29. (i): For \(c_2.X \cap c.X = \emptyset\), we use the fact that \(c_1.X \cap c.X = \emptyset\) follows from \(c_1 \# c\) and \(c_1.X = c_2.X\).

To see that the outflow of \(c_2\) matches the inflow of \(c\), we consider \(x \in c_2.X\) and \(y \in c.X\) and reason as follows:

\[
c_2.\text{out}(x, y) = c_1.\text{out}(x, y) = c.\text{in}(x, y).
\]

The former equality follows from \(c_2.\text{in} = c_1.\text{in}\) together with \(tf(c_1) =_{c_1.in} tf(c_2)\). The second equality is by \(c_1 \# c\).

The inflow is preserved by the assumption, hence we have the following:

\[
c.\text{out}(y, x) = c_1.\text{in}(y, x) = c_2.\text{in}(y, x) .
\]

It remains to show \((c_2 \cup c).\text{flow} = c_2.\text{flow} \cup c.\text{flow}\). We use Bekic’s lemma. Define the target pairing of two functions \(f : A \rightarrow B\) and \(g : A \rightarrow C\) over the same domain \(A\) as the function \((f, g) : A \rightarrow B \times C\) with \((f, g)(a) \equiv (f(a), g(a))\). We compute the flow of \((c_2 \cup c)\) as the least fixed point of a target pairing \((f, g)\) with

\[
f : ((c_2.X \cup c.X) \rightarrow M) \rightarrow c_2.X \rightarrow M
\]

\[
g : ((c_2.X \cup c.X) \rightarrow M) \rightarrow c.X \rightarrow M .
\]

Function \(f\) updates the flow of the nodes in \(c_2\) depending on the flow inflow from \(c\). Function \(g\) is responsible for the flow of the nodes in \(c\). The inflow from the nodes outside \(c_2 \cup c\) is constant. The definition guarantees \((c_2 \cup c).\text{flow} = \text{lfp}(f, g)\).

We curry the former function,

\[
f : (c.X \rightarrow M) \rightarrow (c_2.X \rightarrow M) \rightarrow c_2.X \rightarrow M ,
\]
and obtain, for every \( cval : c.X \to \mathcal{M} \), the function

\[
f(cval) : (c_2.X \to \mathcal{M}) \to c_2.X \to \mathcal{M}.
\]

This function is still monotonic and therefore has a least fixed point. Hence, the function

\[
f^\uparrow : (c.X \to \mathcal{M}) \to c_2.X \to \mathcal{M}
\]

mapping valuation \( cval : c.X \to \mathcal{M} \) to the least fixed point \( \text{lfp}(f(cval)) \) is well-defined.

Bekić’s lemma \([5]\) tells us how to compute least fixed points of target pairings like \( \langle f, g \rangle \) above by successive elimination of the variables. We first determine \( f^\uparrow \), which is a function in \( c.X \to \mathcal{M} \). We plug this function into \( g \) to obtain a function solely in \( c.X \to \mathcal{M} \). To be precise, since \( g \) expects a function from \( (c_2.X \uplus c.X) \to \mathcal{M} \), we pair \( f^\uparrow \) with \( id = id_{c.X \to \mathcal{M}} \) and obtain

\[
\langle f^\uparrow, id \rangle : (c.X \to \mathcal{M}) \to (c_2.X \uplus c.X) \to \mathcal{M}.
\]

We compose this function with \( g \) and get

\[
g \circ \langle f^\uparrow, id \rangle : (c.X \to \mathcal{M}) \to c.X \to \mathcal{M}.
\]

We compute the least fixed point of this composition to obtain the values of the least fixed point of interest on \( c.X \). For the values on \( c_2.X \), we reinsert the \( c.X \)-values into \( f^\uparrow \). Bekić’s lemma guarantees the correctness of this successive elimination procedure:

\[
\text{lfp}(\langle f, g \rangle) = (f^\uparrow(cval), cval)
\]

with \( cval = \text{lfp}(g \circ \langle f^\uparrow, id \rangle) \).

To conclude the proof, we recall that \( tf(c2) = c_{1,in} \circ tf(c1) \). Moreover, for all \( y \in c.X \) and \( x \in c_1.X \) we have

\[
c_{1,in}(y, x) = c.out(y, x) = c.E_{(y,x)}(c.flow(x)).
\]

Together with monotonicity of the edge functions, this implies \( g \circ \langle f^\uparrow, id \rangle = c.flow \circ \langle h^\uparrow, id \rangle \). Here, \( h : ((c_2.X \uplus c.X) \to \mathcal{M}) \to c_2.X \to \mathcal{M} \) is the transformer derived from \( c_1 \) in the same way \( f \) was derived from \( c_2 \). We thus have for all \( x \in c.X \):

\[
(c_2 \uplus c).flow(x)
\]

( Definition flow, f, g ) = \( \text{lfp}(\langle f, g \rangle)(x) \)

( Bekić’s lemma, x \in c.X ) = \( \text{lfp}(g \circ \langle f^\uparrow, id \rangle)(x) \)

( tf(c2) = c_{1,in} \circ tf(c1), see above ) = \( \text{lfp}(g \circ \langle h^\uparrow, id \rangle)(x) \)

( Bekić’s lemma, x \in c.X ) = \( \text{lfp}(h, g)(x) \)

( Definition flow, f, g ) = \( (c_2 \uplus c).flow(x) \)

( c1 \# c, x \in c.X ) = \( c.flow(x) \).

We argue that also for nodes \( x \in c_2.X \) that we have the equality \( (c_2 \uplus c).flow(x) = c_2.flow(x) \), as follows:

\[
(c_2 \uplus c).flow(x)
\]

( Definition flow, f, g ) = \( \text{lfp}(\langle f, g \rangle)(x) \)

( Bekić’s lemma, x \in c_2.X ) = \( [f^\uparrow(cval)](x) \)

( See above ) = \( [f^\uparrow(c.flow)](x) \)

( See below ) = \( c_2.flow(x) \).
To see the last equality, note that we have $c_2.in(y, x) = c.out(y, x) = c.E_{(y, x)}(c.flow(x))$, for all $y \in c.X$. Hence, $c_2.flow$, which we compute from the inflow, is the least fixed point of $f$ computed with $c.flow$ fixed.

(ii). Follows with a similar but simpler application of Bekić’s lemma. □

**Proof of Lemma 34.** We show the individual cases.

(i): We apply Lemma 29 to derive that $\llbracket up \rrbracket(c) \# c'$ holds. To see that the preconditions in the lemma are met, note that we have $c \# c'$ by assumption, $\llbracket up \rrbracket(c).X = c.X$ and $\llbracket up \rrbracket(c).in = c.in$ because the semantics does not abort, and the application of updates neither changes the set of nodes nor the inflow, and $tf(c) = tf(\llbracket up \rrbracket(c))$ because the update does not abort.

(ii): Since the separating conjunctions on both sides of the equality are defined by (i) resp. the assumption, the sets of nodes and the inflows coincide. The sets of edges coincide, because $\text{dom}(up) \subseteq c.X \times \mathbb{N}$ as the update does not abort on $c$.

(iii): With the previous argument, we arrive at: $\text{dom}(up) \subseteq (c.X \uplus c'.X) \times \mathbb{N} = (c \ast c').X \times \mathbb{N}$. Here, disjointness and the separating conjunction rely on $c \# c'$. For the transformer, we use

$$tf((c \ast c')[up]) = tf(\llbracket up \rrbracket(c) \ast c') = tf(c \ast c') .$$

The former equality is by (ii). The latter is Lemma 29 and we already argued that the conditions are met.

(iv) : By (iii), we have $\llbracket up \rrbracket(c \ast c') = (c \ast c')[up]$. The desired equality is by (ii). □

**Proof of Lemma 28.** Since separation algebras are closed under Cartesian products, the product operation on flow graphs is associative and commutative and $(h_2, c_2)$ is the neutral element.

We show $(h_2, c_2) \in FG$. For the nodes, we have

$$h_2.X = \varnothing = c_2.X .$$

The empty edge function $c.E = \varnothing$ is trivially induced (the universal quantifier is over an empty set).

We show closedness: if $fg_1, fg_2 \in FG$ and $fg_1 \# fg_2$, then we also have $fg_1 \ast fg_2 \in FG$. Due to the Cartesian product construction, we have $(fg_1.h \ast fg_2.h, fg_1.c \ast fg_2.c) \in HG \times FC$. Note that this uses the fact that $fg_1 \# fg_2$ implies $fg_1.h \# fg_2.h$ and $fg_1.c \# fg_2.c$.

It remains to show that the constraints on nodes and edges hold. For the nodes, we have

$$(fg_1.h \ast fg_2.h).X = fg_1.h.X \uplus fg_2.h.X = fg_1.c.X \uplus fg_2.c.X = (fg_1.c \ast fg_2.c).X .$$

The first equality is by the definition of products on heap graphs, the second is the assumption $fg_1, fg_2 \in FG$, and the last is the definition of products on flow constraints. For the edge function,
we consider $x \in f_{g_1}.h.X$ and $y \in \mathbb{N}$. For $x \in f_{g_2}.h.X$, the reasoning is similar:

\[
\sum_{psel \in Psel} \text{gen}(psel, (f_{g_1}.h \ast f_{g_2}.h).dval(x))
\]

\[
= (1) \sum_{psel \in Psel} \text{gen}(psel, (f_{g_1}.h.dval \uplus f_{g_2}.h.dval)(x))
\]

\[
= (2) \sum_{psel \in Psel} \text{gen}(psel, f_{g_1}.h.dval(x))
\]

\[
= (3) f_{g_1}.c.E(x, y)
\]

\[
= (4) (f_{g_1}.c.E \uplus f_{g_2}.c.E)(x, y)
\]

\[
= (5) (f_{g_1}.c \ast f_{g_2}.c).E(x, y)
\]

where the equalities are due to: (1) the definition of products of heap graphs, (2) $x \in f_{g_1}.h.X$ together with disjointness, (3) the fact that $f_{g_1}, f_{g_2}$ are flow graphs, (4) $x \in f_{g_1}.h.X$ together with union of functions, and (5) the definition of products of flow constraints. \qed
