An Infinitary Proof Theory of Linear Logic Ensuring Fair Termination in the Linear $\pi$-Calculus

Luca Ciccone

Luca Padovani
Università di Torino, Italy

Abstract

Fair termination is the property of programs that may diverge “in principle” but that terminate “in practice”, i.e. under suitable fairness assumptions concerning the resolution of non-deterministic choices. We study a conservative extension of $\mu$MALL$^\infty$, the infinitary proof system of the multiplicative additive fragment of linear logic with least and greatest fixed points, such that cut elimination corresponds to fair termination. Proof terms are processes of $\pi$LIN, a variant of the linear $\pi$-calculus with (co)recursive types into which binary and (some) multiparty sessions can be encoded. As a result we obtain a behavioral type system for $\pi$LIN (and indirectly for session calculi through their encoding into $\pi$LIN) that ensures fair termination: although well-typed processes may engage in arbitrarily long interactions, they are fairly guaranteed to eventually perform all pending actions.

1 Introduction

The linear $\pi$-calculus $[28]$ is a typed refinement of Milner’s $\pi$-calculus in which linear channels can be used only once, for a one-shot communication. As it turns out, the linear $\pi$-calculus is the fundamental model underlying a broad family of communicating processes. In particular, all binary sessions $[22, 23, 25]$ and some multiparty sessions $[24]$ can be encoded into the linear $\pi$-calculus $[27, 6, 11, 9]$. Sessions are private communication channels linking two or more processes and whose usage is disciplined by a session type, a type representing a structured communication protocol. In all session type systems, session endpoints are linearized channels that can be used repeatedly but in a sequential manner. The key insight for encoding sessions into the linear $\pi$-calculus is to represent linearized channels as chains of linear channels: when some payload is transmitted over a linear channel, it can be paired with another linear channel on which the subsequent interaction takes place.

In this work we propose a type system for $\pi$LIN, a linear $\pi$-calculus with (co)recursive types, such that well-typed processes are fairly terminating. Fair termination $[21, 17]$ is a liveness property stronger than lock freedom $[26, 55]$ – i.e. the property that every pending action can be eventually performed – but weaker than termination. In particular, a fairly terminating program may diverge, but all of its infinite executions are considered “unfair” – read impossible or unrealistic – and so they can be ignored insofar termination is concerned. A simple example of fairly terminating program is that modeling a repeated interaction between a buyer and a seller in which the buyer may either pay the seller and terminate or may add an item to the shopping cart and then repeat the same behavior. In principle, there
Fair Termination in the Linear $\pi$-Calculus

is an execution of the program in which the buyer keeps adding items to the shopping cart and never pays. In practice, this behavior is considered unfair and the program terminates under the fairness assumption that the buyer eventually pays the seller.

Our type system is a conservative extension of $\mu$MALL$^\infty$ [4, 16, 3], the infinitary proof system for the multiplicative additive fragment of linear logic with least and greatest fixed points. In fact, the modifications we make to $\mu$MALL$^\infty$ are remarkably small: we add one (standard) rule to deal with non-deterministic choices, those performed autonomously by a process, and we relax the validity condition on $\mu$MALL$^\infty$ proofs so that it only considers the “fair behaviors” of the program it represents. The fact that there is such a close correspondence between the typing rules of $\pi$LIN and the inference rules of $\mu$MALL$^\infty$ is not entirely surprising. After all, there have been plenty of works investigating the relationship between $\pi$-calculus terms and linear logic proofs, from those of Abramsky [1], Bellin and Scott [5] to those on the interpretation of linear logic formulas as session types [15, 43, 7, 31, 39, 37]. Nonetheless, we think that the connection between $\pi$LIN and $\mu$MALL$^\infty$ stands out for two reasons. First, $\pi$LIN is conceptually simpler and more general than the session-based calculi that can be encoded in it. In particular, all the session calculi based on linear logic rely on an asymmetric interpretation of the multiplicative connectives $\otimes$ and $\otimes$ so that $\varphi \otimes \psi$ (respectively, $\varphi \otimes \psi$) is the type of a session endpoint used for sending (respectively, receiving) a message of type $\varphi$ and then used according to $\psi$. In our setting, the connectives $\otimes$ and $\otimes$ retain their symmetry since we interpret $\varphi \otimes \psi$ and $\varphi \otimes \psi$ formulas as the output/input of pairs, in the same spirit of the original encoding of linear logic proofs proposed by Bellin and Scott [5]. This interpretation gives $\pi$LIN the ability of modeling bifurcating protocols of which binary sessions are just a special case. The second reason why $\pi$LIN and $\mu$MALL$^\infty$ get along has to do with the cut elimination result for $\mu$MALL$^\infty$. In finitary proof systems for linear logic, cut elimination may proceed by removing topmost cuts. In $\mu$MALL$^\infty$ there is no such notion as a topmost cut since $\mu$MALL$^\infty$ proofs may be infinite. As a consequence, the cut elimination result for $\mu$MALL$^\infty$ is proved by eliminating bottom-most cuts [3]. This strategy fits perfectly with the reduction semantics of $\pi$LIN — and that of any other conventional process calculus, for that matter — whereby reduction rules act only on the exposed (i.e. unguarded) part of processes but not behind prefixes. As a result, the reduction semantics of $\pi$LIN is completely ordinary, unlike other logically-inspired process calculi that incorporate commuting conversions [43, 31] or other unnatural prefix swapping [5].

In previous work [10] we have proposed a type system ensuring the fair termination of binary sessions. The present work achieves the same objective using a more basic process calculus and exploiting its strong logical connection with $\mu$MALL$^\infty$. In fact, the soundness proof of our type system piggybacks on the cut elimination property of $\mu$MALL$^\infty$. Other session typed calculi based on linear logic with fixed points have been studied by Lindley and Morris [31] and by Derakhshan and Pfenning [14, 13]. The type systems described in these works respectively guarantee termination and strong progress, whereas our type system guarantees fair termination which is somewhat in between these properties. Overall, our type system seems to hit a sweet spot: on the one hand, it is deeply rooted in linear logic and yet it can deal with common communication patterns (like the buyer/seller interaction described above) that admit potentially infinite executions and therefore are out of scope of other logic-inspired type systems; on the other hand, it guarantees lock freedom [26, 33], strong progress [14, Theorem 12.3] and also termination, under a suitable fairness assumption.

The paper continues as follows. Section 2 presents $\pi$LIN and the fair termination property ensured by our type system. Section 3 describes $\pi$LIN types, which are suitably embellished $\mu$MALL$^\infty$ formulas. Section 4 describes the inference rules of $\mu$MALL$^\infty$ rephrased as typing
rules for \( \pi \text{LIN} \). Section 5 identifies the valid typing derivations and states the properties of well-typed processes. Section 6 discusses related work in more detail and Section 7 presents ideas for future developments. Supplementary material, additional examples and proofs can be found in the appendix.

## Syntax and Semantics of \( \pi \text{LIN} \)

In this section we define syntax and reduction semantics of \( \pi \text{LIN} \), a variant of the linear \( \pi \)-calculus \[28\] in which all channels are meant to be used for exactly one communication. The calculus supports (co)recursive data types built using units, pairs and disjoint sums. These data types are known to be the essential ingredients for the encoding of sessions in the linear \( \pi \)-calculus \[27, 11, 40\].

We assume given an infinite set of channels ranged over by \( x, y \) and \( z \). \( \pi \text{LIN} \) processes are coinductively generated by the productions of the grammar shown in Table 1 and their informal meaning is given below. A **link** \( x \leftrightarrow y \) acts as a linear forwarder \[18\] that forwards a single message either from \( x \) to \( y \) or from \( y \) to \( x \). The uncertainty in the direction of the message is resolved once the term is typed and the polarity of the types of \( x \) and \( y \) is fixed (Section 4). The term **case** \( x \{ \} \) represents a process that receives an empty message from \( x \) and then fails. This form is only useful in the metatheory: the type system guarantees that well-typed processes never fail, since it is not possible to send empty messages. The term \( \pi() \) models a process that sends the unit on \( x \), effectively indicating that the interaction is terminated, whereas \( x().P \) models a process that receives the unit from \( x \) and then continues as \( P \). The term \( \pi(y, z)(P \parallel Q) \) models a process that creates two new channels \( y \) and \( z \), sends them in a pair on channel \( x \) and then forks into two parallel processes \( P \) and \( Q \). Dually, \( x(y, z).P \) models a process that receives a pair containing two channels \( y \) and \( z \) from channel \( x \) and then continues as \( P \). The term \( \text{in}i\pi(y).P \) models a process that creates a new channel \( y \) and sends \( \text{in}i(y) \) (that is, the \( i \)-th injection of \( y \) in a disjoint sum) on \( x \). Dually, **case** \( x(y)\{P_1, P_2\} \) receives a disjoint sum from channel \( x \) and continues as either \( P_1 \) or \( P_2 \) depending on the tag \( i \), it has been built with. For clarity, in some examples we will use more descriptive labels such as **add** and **pay** instead of \( \text{in}1 \) and \( \text{in}2 \). The terms \( \text{rec} \pi(y).P \) and \( \text{corec} \pi(x(y).P \) model processes that respectively send and receive a new channel \( y \) and then continue as \( P \). They do not contribute operationally to the interaction being modeled, but they indicate the points in a program where (co)recursive types are unfolded. A term \( (x)(P \parallel Q) \) denotes the parallel composition of two processes \( P \) and \( Q \) that interact through the fresh channel \( x \). Finally, the term \( P \oplus Q \) models a non-deterministic choice between two behaviors \( P \) and \( Q \).

\( \pi \text{LIN} \) binders are easily recognizable because they enclose channel names in round parentheses. Note that all outputs are in fact **bound outputs**. The output of free channels can be modeled by combining bound outputs with links \[31\]. For example, the output \( \pi(y, z) \) of
16:4 Fair Termination in the Linear $\pi$-Calculus

a pair of free channels $y$ and $z$ can be modeled as the term $\pi(y', z')(y \leftrightarrow y' \parallel z \leftrightarrow z')$. We identify processes modulo renaming of bound names, we write $\text{fn}(P)$ for the set of channel names occurring free in $P$ and we write $\{y/x\}$ for the capture-avoiding substitution of $y$ for the free occurrences of $x$. We impose a well-formedness condition on processes so that, in every sub-term of the form $\pi(y, z)(P \parallel Q)$, we have $y \notin \text{fn}(Q)$ and $z \notin \text{fn}(P)$.

We omit any concrete syntax for representing infinite processes. Instead, we work directly with infinite trees obtained by corecursively unfolding contractive equations of the form $A(x_1, \ldots, x_n) = P$. For each such equation, we assume that $\text{fn}(P) \subseteq \{x_1, \ldots, x_n\}$ and we write $A(y_1, \ldots, y_n)$ for its unfolding $P\{y_i/x_i\}_{1 \leq i \leq n}$. Appendix E.1 describes the changes for supporting a more conventional (but slightly heavier) handling of infinite processes.

▸ Notation 1. To reduce clutter due to the systematic use of bound outputs, by convention we omit the continuation called $y$ in Table 1 when its name is chosen to coincide with that of the channel $x$ on which $y$ is sent/received. For example, with this notation we have $x(z).P = x(z, x).P$ and $\text{in}_1 \pi.P = \text{in}_n \pi(x).P$ and case $x(P, Q) = \text{case } x(x)(P, Q)$.

A welcome side effect of adopting Notation 1 is that it gives the illusion of working with a session calculus in which the same channel name over and over is widespread in session-based functional languages [20, 35] as it provides a simple way of “updating the type” of a session endpoint after each use.

▸ Example 2. Below we model the interaction informally described in Section 1 between buyer and seller using the syntactic sugar defined in Notation 1.

$$(x)(\text{Buyer}(x) \parallel \text{Seller}(x, y)) \quad \text{where} \quad \text{Buyer}(x) = \text{rec } \pi.(\text{add } \pi.\text{Buyer}(x) \parallel \text{pay } \pi.\pi())$$

$$\text{Seller}(x, y) = \text{corec } x.\text{case } x\{\text{Seller}(x, y), x().\pi()\}$$

At each round of the interaction, the buyer decides whether to add an item to the shopping cart and repeat the same behavior (left branch of the choice) or to pay the seller and terminate (right branch of the choice). The seller reacts dually and signals its termination by sending a unit on the channel $y$. As we will see in Section 4, rec $\pi$ and corec $x$ identify the points within processes where (co)recursive types are unfolded.

If we were to define Buyer using distinct bound names we would write an equation like

$$\text{Buyer}(x) = \text{rec } \pi(y).\text{(add } \pi(z).\text{Buyer}(z) \parallel \text{pay } \pi(z).\pi())$$

and similarly for Seller.

The operational semantics of the calculus is given in terms of the structural precongruence relation $\subseteq$ and the reduction relation $\rightarrow$ defined in Table 2. As usual, structural precongruence relates processes that are syntactically different but semantically equivalent. In particular, S-LINK states that linking $x$ with $y$ is the same as linking $y$ with $x$, whereas S-COMM and S-ASSOC state the expected commutativity and associativity laws for parallel composition. Concerning the latter, the side condition $x \in \text{fn}(Q)$ makes sure that $Q$ (the process brought closer to $P$ when the relation is read from left to right) is indeed connected with $P$ by means of the channel $x$. Note that S-ASSOC only states the right-to-left associativity of parallel composition and that the left-to-right associativity law $(x)((y)(P \parallel Q))R \subseteq (y)(P \parallel (x)(Q \parallel R))$ is derivable when $x \in \text{fn}(Q)$. The reduction relation is mostly unremarkable. Links are
weakly terminating which a run is tantly, it provides us with the key proof principle for the soundness of our type system. but it is fairly terminating (all the fair executions are finite). and finite. So, the system in Example 2 is not terminating (it admits an infinite execution) shopping cart forever and never pays the seller is unfair; any other run of the system is fair of the system modeled in Example 2: the (only) run in which the buyer adds items to the process that always has the chance to terminate but systematically avoids doing so. Think here is an instance of the run corresponding to different fairness assumptions \([17, 29, 42]\). The notion of fair run used in between termination and weak termination in which only the “fair” runs of a process are properties for processes. In particular, \(P \rightarrow \omega\) stands for the lowest transfinite ordinal number and \(o\) ranges over the elements of \(\omega + 1\).

**Definition 3 (run).** A run of \(P\) is a sequence \((P_i)_{i\in \omega}\) where \(o \in \omega + 1\) and \(P_0 = P\) and \(P_i \rightarrow P_{i+1}\) for all \(i + 1 \in o\) and either the sequence is infinite or it ends with a stuck process.

Hereafter we use \(\rho\) to range over runs. Using runs we can define a range of termination properties for processes. In particular, \(P\) is terminating if all of its runs are finite and \(P\) is weakly terminating if it has a finite run. Fair termination is a termination property somewhat in between termination and weak termination in which only the “fair” runs of a process are taken into account insofar its termination is concerned. There exist several notions of fair run corresponding to different fairness assumptions \([17, 29, 42]\). The notion of fair run used here is an instance of the fair reachability of predicates by Queille and Sifakis \([38]\).

**Definition 4 (fair termination).** A run is fair if it contains finitely many weakly terminating processes. We say that \(P\) is fairly terminating if every fair run of \(P\) is finite.

To better understand our notion of fair run, it may be useful to think of the cases in which a run is not fair. An unfair run is necessarily infinite and describes the execution of a process that always has the chance to terminate but systematically avoids doing so. Think of the system modeled in Example 2 the (only) run in which the buyer adds items to the shopping cart forever and never pays the seller is unfair; any other run of the system is fair and finite. So, the system in Example 2 is not terminating (it admits an infinite execution) but it is fairly terminating (all the fair executions are finite).

The following result characterizes fair termination without using fair runs. Most importantly, it provides us with the key proof principle for the soundness of our type system.
Fair Termination in the Linear π-Calculus

Theorem 5 (proof principle for fair termination). \( P \) is fairly terminating if and only if \( P \Rightarrow Q \) implies that \( Q \) is weakly terminating.

Theorem 5 says that any reasonable type system that ensures weak process termination also ensures fair process termination. By “reasonable” we mean a type system for which type preservation (also know as subject reduction) holds, which is usually the case. Indeed, if we consider a well-typed process \( P \) such that \( P \Rightarrow Q \), we can deduce that \( Q \) is also well typed. Now, the soundness of the type system guarantees that \( Q \) is weakly terminating. By applying Theorem 5 from right to left, we conclude that every well-typed \( P \) is fairly terminating.

3 Formulas and Types

The types of πLIN are built using the multiplicative additive fragment of linear logic enriched with least and greatest fixed points. In this section we specify the syntax of types along with all the auxiliary notions that are needed to present the type system and prove its soundness.

The syntax of pre-formulas relies on an infinite set of propositional variables ranged over by \( X \) and \( Y \) and is defined by the grammar below:

Pre-formula \( \varphi, \psi ::= 0 | T | 1 | \bot \mid \varphi \otimes \psi \mid \varphi \& \psi \mid \varphi \otimes \psi \mid \varphi \otimes \psi \mid \mu X.\varphi \mid \nu X.\varphi \mid X \)

As usual, \( \mu \) and \( \nu \) are the binders of propositional variables and the notions of free and bound variables are defined accordingly. We assume that the body of fixed points extends as much as possible to the right of a pre-formula, so \( \mu X.X \) means \( \mu X.(X \uplus 1) \) and not \( (\mu X.X) \uplus 1 \). We write \( \{\varphi/X\} \) for the capture-avoiding substitution of all free occurrences of \( X \) with \( \varphi \). We write \( \varphi^\perp \) for the dual of \( \varphi \), which is the involution defined by the equations

\[
0^\perp = T \quad (\varphi \otimes \psi)^\perp = \varphi^\perp \& \psi^\perp \quad (\mu X.\varphi)^\perp = \nu X.\varphi^\perp \quad X^\perp = X
\]

A formula is a closed pre-formula. In the context of πLIN, formulas describe how linear channels are used. Positive formulas (those built with the constants \( 0 \) and \( 1 \), the connectives \( \otimes \) and \( \& \) and the least fixed point) indicate output operations whereas negative formulas (the remaining forms) indicate input operations. The formulas \( \varphi \otimes \psi \) and \( \varphi \& \psi \) describe a linear channel used for sending/receiving a tagged channel of type \( \varphi \) or \( \psi \). The tag (either \( \text{in}_1 \) or \( \text{in}_2 \)) distinguishes between the two possibilities. The formulas \( \varphi \otimes \psi \) and \( \varphi \otimes \psi \) describe a linear channel used for sending/receiving a pair of channels of type \( \varphi \) and \( \psi \); \( \mu X.\varphi \) and \( \nu X.\varphi \) describe a linear channel used for sending/receiving a channel of type \( \varphi \{\mu X.\varphi/X\} \) or \( \varphi\{\nu X.\varphi/X\} \) respectively. The constants \( 1 \) and \( \bot \) describe a linear channel used for sending/receiving the unit. Finally, the constants \( 0 \) and \( T \) respectively describe channels on which nothing can be sent and from which nothing can be received.

Example 6. Looking at the structure of Buyer and Seller in Example 2, we can make an educated guess on the type of the channel \( x \) they use. Concerning \( x \), we see that it is used according to \( \varphi \equiv \mu X.X \otimes 1 \) in Buyer and according to \( \psi \equiv \nu X.X \& \bot \) in Seller. Note that \( \varphi = \psi^\perp \), suggesting that Buyer and Seller may interact correctly when connected.

We write \( \preceq \) for the subformula ordering, that is the least partial order such that \( \varphi \preceq \psi \) if \( \varphi \) is a subformula of \( \psi \). For example, consider \( \varphi \equiv \mu X.\nu Y.X \otimes Y \) and \( \psi \equiv \nu Y.\varphi \otimes Y \). Then we have \( \varphi \preceq \psi \) and \( \psi \not\preceq \varphi \). When \( \Phi \) is a set of formulas, we write \( \min \Phi \) for its \( \preceq \)-minimum formula if it is defined. Occasionally we let * stand for an arbitrary binary connective \( \otimes \), \( \& \), \( \otimes \) and \( \& \) and \( \sigma \) stand for an arbitrary fixed point operator \( \mu \) or \( \nu \).
When two πLIN processes interact on some channel x, they may exchange other channels on which their interaction continues. We can think of these subsequent interactions stemming from a shared channel x as being part of the same conversation (the rich literature on sessions [22, 25] builds on this idea [11]). The soundness proof of the type system is heavily based on the proof of the cut elimination property of μMALL∞, which relies on the ability to uniquely identify the types of the channels that belong to the same conversation and to trace conversations within typing derivations. Following the literature on μMALL∞ [11, 10], we annotate formulas with addresses. We assume an infinite set A of atomic addresses, A⊥ being the set of their duals such that A ∩ A⊥ = ∅ and A⊥⊥ = A. We use a and b to range over elements of A ∪ A⊥. An address is a string aw where w ∈ {î, l, r}*. The dual of an address is defined as (aw)⊥ = a⊥w. We use α and β to range over addresses, we write ⊑ for the prefix relation on addresses and we say that α and β are disjoint if α ⊑ β and β ⊑ α.

A type is a formula ϕ paired with an address α written ϕα. We use S and T to range over types and we extend to types several operations defined on formulas: we use logical connectives to compose types so that ϕα1 ⊗ ϕα2 ≡ (ϕ ⊗ ψ)α and σX.ϕα1 ≡ (σX.ϕ)α; the dual of a type is obtained by dualizing both its formula and its address, that is (ϕα)⊥ ≡ ϕα⊥; type substitution preserves the address in the type within which the substitution occurs, but forgets the address of the type being substituted, that is ϕα{ψ|β/X} ≡ ϕ{ψ/X}α.

We often omit the address of constants (which represent terminated conversations) and we write S for the formula obtained by forgetting the address of S. Finally, we write ⊒ for the least reflexive relation on types such that S1 ⊒ S2 ⊒ S1 and σX.S ⊒ S{σX.S/X}.

Example 7. Consider once again the formula ϕ ≡ μX.X ⊕ 1 that describes the behavior of Buyer (Example 6) and let a be an arbitrary atomic address. We have ϕa ⊒ (ϕ ⊕ 1)a ⊒ ϕa ⊒ (ϕ ⊕ 1)a ⊒ 1a

where the fact that the types in this sequence all share a common non-empty prefix ‘a’ indicates that they belong to the same conversation. Note how the symbols i, l and r composing an address indicate the step taken in the syntax tree of types for making a move in this sequence: i means “left”, when a fixed point operator is unfolded, whereas l and r mean “left” and “right”, when the corresponding branch of a connective is selected. ■

4 Type System

We now present the typing rules for πLIN. As usual we introduce typing contexts to track the type of the names occurring free in a process. A typing context is a finite map from names to types written x1 : S1, ..., xn : Sn. We use Γ and Δ to range over contexts, we write dom(Γ) for the domain of Γ and Γ,Δ for the union of Γ and Δ when dom(Γ) ∩ dom(Δ) = ∅. Typing judgments have the form P ⊢ Γ. We say that P is quasi typed in Γ if the judgment P ⊢ Γ is coinductively derivable using the rules shown in Table 3 and described below. For the time being we say “quasi typed” and not “well typed” because some infinite derivations using the rules in Table 3 are invalid. Well-typed processes are quasi-typed processes whose typing derivation satisfies some additional validity conditions that we detail in Section 5.

Rule [AX] states that a link x ↔ y is quasi typed provided that x and y have dual types, but not necessarily dual addresses. Rule [CUT] states that a process composition (x)(P || Q) is quasi typed provided that P and Q use the linear channel x in complementary ways, one according to some type S and the other according to the dual type S⊥. Note that the context Γ,Δ in the conclusion of the rule is defined provided that Γ and Δ have disjoint domains. This condition entails that P and Q do not share any channel other than x ensuring that the
Table 3 Typing rules for \( \pi \text{-LIN} \).

\[
\begin{array}{ll}
\text{\( x \leftrightarrow y \vdash x : \varphi_\alpha, y : \varphi_\beta \) [AX]} & \frac{P \vdash \Gamma, x : S}{Q \vdash \Delta, x : S^\perp} [\text{cut}] \\
\text{\( \text{case } x \{y\} \vdash \Gamma, x : \top \) [\text{T}]} & \frac{P \vdash \Gamma}{x().P \vdash \Gamma, x : \bot} [\text{\( \bot \)}] \\
\frac{P \vdash \Gamma, y : S, z : T}{x(y, z).P \vdash \Gamma, x : S \otimes T} [\text{\( S \)}] & \frac{P \vdash \Gamma, y, z \vdash S \quad Q \vdash \Delta, z : T}{\overline{x(\nu X.S/y)} \vdash \Gamma, x : S \otimes T} [\text{\( \nu X.S \)}] \\
\frac{P \vdash \Gamma, y : S \quad Q \vdash \Gamma, y : T}{P \vdash \Gamma \{y\} \{Q, y\} \vdash \Gamma, x : S \& T} [\text{\( \& \)}] & \frac{P \vdash \Gamma, y : S \quad Q \vdash \Gamma}{P \vdash \Gamma \{y\} \{Q, y\} \vdash \Gamma, x : S \oplus T} [\text{\( \bigoplus \)}] \\
\frac{P \vdash \Gamma, y : S\{\nu X.S/X\} \{y\}}{\text{\( \text{corec } x(y).P \vdash \Gamma, x : \nu X.S \)} [\nu]} & \frac{P \vdash \Gamma, y : S\{\nu X.S/X\} \{y\}}{\text{\( \text{rec } \overline{x(y)}.P \vdash \Gamma, x : \mu X.S \)} [\mu]} & \frac{P \vdash \Gamma}{P \vdash \Gamma \{Q \vdash \Gamma \}} [\text{\( \text{choice} \)}] \\
\end{array}
\]

interaction between \( P \) and \( Q \) may proceed without deadlocks. Rule [\text{\( \bot \)}] deals with a process that receives an empty message from channel \( x \). Since this cannot happen, we allow the process to be quasi typed in any context. Rules [\text{\( \nu X.S \)}] and [\text{\( \nu X.S \)}] concern the exchange of units. The former rule states that \( \overline{x()} \) is quasi typed in a context that contains a single association for the \( x \) channel with type \( \bot \), whereas the latter rule removes \( x \) from the context (hence from the set of usable channels), requiring the continuation process to be quasi typed in the remaining context. Rules [\text{\( \nu X.S \)}] and [\text{\( \nu X.S \)}] concern the exchange of pairs. The former rule requires the two forked processes \( P \) and \( Q \) to be quasi typed in the respective contexts enriched with associations for the continuation channels \( y \) and \( z \) being created. The latter rule requires the continuation process to be quasi typed in a context enriched with the channels extracted from the received pair. Rules [\text{\( \bigoplus \)}] and [\text{\( \bigoplus \)}] deal with the exchange of disjoint sums in the expected way. Rules [\text{\( \nu X.S \)}] and [\text{\( \nu X.S \)}] deal with fixed point operators by unfolding the (co)recursive type of the channel \( x \). As in \( \mu \text{MALL}^\infty \), the two rules have exactly the same structure despite the fact that the two fixed point operators being used are dual to each other. Clearly, the behavior of least and greatest fixed points must be distinguished by some other means, as we will see in Section 5 when discussing the validity of a typing derivation. Finally, [\text{\( \text{choice} \)}] deals with non-deterministic choices by requiring that each branch of a choice must be quasi typed in exactly the same typing context as the conclusion.

Besides the structural constraints imposed by the typing rules, we implicitly require that the types in the range of all typing contexts have pairwise disjoint addresses. This condition ensures that it is possible to uniquely trace a communication protocol in a typing derivation: if we have two channels \( x \) and \( y \) associated with two types \( \varphi_\alpha \) and \( \psi_\beta \) such that \( \alpha \sqsubseteq \beta \), then we know that \( y \) is a continuation resulting from a communication that started from \( x \). In a sense, \( x \) and \( y \) represent different moments in the same conversation.

Example 8 (buyer and seller). Let us show that the system described in Example 2 is quasi typed. To this aim, let \( \varphi \equiv \mu X.X \oplus \bot \) and \( \psi \equiv \nu X.X \& \bot \) respectively be the formulas describing the behavior of Buyer and Seller on the channel \( x \). Note that \( \psi = \varphi^+ \) and let \( a \)
be an arbitrary atomic address. We derive

\[
\begin{align*}
\text{Buyer}(x) & \vdash x : \phi_a \\
\text{add } \pi. \text{Buyer}(x) & \vdash x : (\phi + 1)_a \\
\text{pay } \pi. \text{Buyer}(x) & \vdash x : (\phi + 1)_a \\
\text{Buyer}(x) & \vdash x : \phi_a
\end{align*}
\]

and also

\[
\begin{align*}
\text{Seller}(x, y) & \vdash x : \psi_{a^{+1}}, y : 1 \\
x() & \vdash x : 1, y : 1 \\
\text{case } \{ \text{Seller}(x, y), x(), x() \} & \vdash x : (\psi \& \bot)_{a^{+1}}, y : 1 \\
\text{Seller}(x, y) & \vdash x : \psi_{a^{+1}}, y : 1
\end{align*}
\]

showing that Buyer and Seller are quasi typed. Note that both derivations are infinite, but for dual reasons. In Buyer the infinite branch corresponds to the behavior in which Buyer chooses to add one more item to the shopping cart. This choice is made independently of the behavior of other processes in the system. In Seller, the infinite branch corresponds to the behavior in which Seller receives one more add message from Buyer. By combining these derivations we obtain

\[
\begin{align*}
\text{Buyer}(x) & \vdash x : \phi_a \\
\text{Seller}(x, y) & \vdash x : \psi_{a^{+1}}, y : 1 \\
(x)(\text{Buyer}(x) \parallel \text{Seller}(x, y)) & \vdash y : 1
\end{align*}
\]

showing that the system as a whole is quasi typed.

As we have anticipated, there exist infinite typing derivations that are unsound from a logical standpoint, because they allow us to prove 0 or the empty sequent. For example, if we consider the non-terminating process \(\Omega(x) = \Omega(x) \oplus \Omega(x)\) we obtain the infinite derivation

\[
\begin{align*}
\Omega(x) & \vdash x : 0 \\
\Omega(x) & \vdash x : 0 \\
\Omega(x) & \vdash x : 0
\end{align*}
\]

showing that \(\Omega(x)\) is quasi typed. As illustrated by the next example, there exist non-terminating processes that are quasi typed also in logically sound contexts.

\[\blacktriangleright\] \textbf{Example 9 (compulsive buyer).} Consider the following variant of the Buyer process

\[
\text{Buyer}(x, z) = \text{rec } \pi. \text{add } \pi. \text{Buyer}(x, z)
\]

that models a “compulsive buyer”, namely a buyer that adds infinitely many items to the shopping cart but never pays. Using \(\phi \equiv \mu X. X \oplus 1\) and an arbitrary atomic address \(a\) we can build the following infinite derivation

\[
\begin{align*}
\text{Buyer}(x) & \vdash x : \phi_a \\
\text{add } \pi. \text{Buyer}(x) & \vdash x : (\phi + 1)_a \\
\text{Buyer}(x) & \vdash x : \phi_a
\end{align*}
\]
showing that this process is quasi typed. By combining this derivation with the one for Seller in Example 8 we obtain a derivation establishing that \((x)(Buyer(x) \parallel Seller(x, y))\) is quasi typed in the context \(y : 1\), although this composition cannot terminate.

5 From Quasi-Typed to Well-Typed Processes

To rule out unsound derivations like those in Equation 1 and Example 9 it is necessary to impose a validity condition on derivations \[16\]. Roughly speaking, \(\mu\mathbb{MALL}^\infty\)'s validity condition requires every infinite branch of a derivation to be supported by the continuous unfolding of a greatest fixed point. In order to formalize this condition, we start by defining threads, which are sequences of types describing sequential interactions at the type level.

Definition 10 (thread). A thread of \(S\) is a sequence of types \((S_i)_{i \in \omega}\) for some \(\omega + 1\) such that \(S_0 = S\) and \(S_i \rightarrow S_{i+1}\) whenever \(i + 1 \in \omega\).

Hereafter we use \(t\) to range over threads. For example, if we consider \(\varphi \triangleq \mu X . X \oplus 1\) from Example 2 we have that \(t \equiv (\varphi_a, (\varphi \oplus 1)_{a_1}, \varphi_{a_1}, \ldots)\) is an infinite thread of \(\varphi_a\). A thread is stationary if it has an infinite suffix of equal types. The above thread \(t\) is not stationary.

Among all threads, we are interested in finding those in which a \(\nu\)-formula is unfolded infinitely often. These threads, called \(\nu\)-threads, are precisely defined thus:

Definition 11 (\(\nu\)-thread). Let \(t = (S_i)_{i \in \omega}\) be an infinite thread, let \(\mathcal{T}\) be the corresponding sequence \((S_i)_{i \in \omega}\) of formulas and let \(inf(t)\) be the set of elements of \(\mathcal{T}\) that occur infinitely often in \(\mathcal{T}\). We say that \(t\) is a \(\nu\)-thread if \(\min inf(t)\) is defined and is a \(\nu\)-formula.

If we consider the infinite thread \(t\) above, we have \(\text{inf}(t) = \{\varphi, \varphi \oplus 1\}\) and \(\min \text{inf}(t) = \varphi\), so \(t\) is not a \(\nu\)-thread because \(\varphi\) is not a \(\nu\)-formula. Consider instead \(\varphi \triangleq \nu X . Y . X \oplus Y\) and \(\psi \triangleq \mu Y . \varphi \oplus Y\) and observe that \(\psi\) is the “unfolding” of \(\varphi\). Now \(t_1 \equiv (\varphi_a, (\varphi \oplus 1)_{a_1}, \varphi_{a_1}, \ldots)\) is a thread of \(\varphi_a\) such that \(\inf(t_1) = \{\varphi, \psi, \varphi \oplus \psi\}\) and we have \(\min \text{inf}(t_1) = \varphi\) because \(\varphi \preceq \psi\), so \(t_1\) is a \(\nu\)-thread. If, on the other hand, we consider the thread \(t_2 \equiv (\varphi_a, (\varphi \oplus \psi)_{a_1}, (\varphi \oplus 1)_{a_1}, \ldots)\) such that \(\inf(t_2) = \{\psi, \varphi \oplus \psi\}\) we have \(\min \text{inf}(t_2) = \psi\) because \(\varphi \preceq \psi \oplus \psi\), so \(t_2\) is not a \(\nu\)-thread. Intuitively, the \(\preceq\)-minimum formula among those that occur infinitely often in a thread is the outermost fixed point operator that is being unfolded infinitely often. It is possible to show that this minimum formula is always well defined \[16\]. If such minimum formula is a greatest fixed point then the thread is a \(\nu\)-thread.

Now we proceed by identifying threads along branches of typing derivations. To this aim, we provide a precise definition of branch.

Definition 12 (branch). A branch of a typing derivation is a sequence \((P_i \vdash \Gamma_i)_{i \in \omega}\) of judgments for some \(\omega + 1\) such that \(P_0 \vdash \Gamma_0\) occurs somewhere in the derivation and \(P_{i+1} \vdash \Gamma_{i+1}\) is a premise of the rule application that derives \(P_i \vdash \Gamma_i\) whenever \(i + 1 \in \omega\).

An infinite branch is valid if supported by a \(\nu\)-thread that originates somewhere therein.

Definition 13 (valid branch). Let \(\gamma = (P_i \vdash \Gamma_i)_{i \in \omega}\) be an infinite branch in a derivation. We say that \(\gamma\) is valid if there exists \(j \in \omega\) such that \((S_k)_{k \geq j}\) is a non-stationary \(\nu\)-thread and \(S_k\) is in the range of \(\Gamma_k\) for every \(k \geq j\).

For example, the infinite branch in the typing derivation for Seller of Example 2 is valid since it is supported by the \(\nu\)-thread \((\psi_a, (\psi \& \bot)_{a+1}, \psi_{a+1}, \ldots)\) where \(\psi \equiv \nu X . X \& \bot\) happens to be the \(\preceq\)-minimum formula that is unfolded infinitely often. On the other hand,
the infinite branch in the typing derivation for Buyer of Example 9 is invalid, because the only infinite thread in it is \((\varphi, (T \oplus 1)_a, \varphi_n, \ldots)\) which is not a \(\nu\)-thread.

A \(\mu\text{MALL}^\infty\) derivation is valid if so is every infinite branch in it \([4, 10]\). For the purpose of ensuring fair termination, this condition is too strong because some infinite branches in a typing derivation may correspond to unfair executions that, by definition, we neglect insofar its termination is concerned. For example, the infinite branch in the derivation for Buyer of Example 5 corresponds to an unfair run in which the buyer insists on adding items to the shopping cart, despite it periodically has a chance of paying the seller and terminate the interaction. That typing derivation for Buyer would be considered an invalid proof in \(\mu\text{MALL}^\infty\) because the infinite branch is not supported by a \(\nu\)-thread (in fact, there is a \(\mu\)-formula that is unfolded infinitely many times along that branch, as in Example 9).

It is generally difficult to understand if a branch corresponds to a fair or unfair run because the branch describes the evolution of an incomplete process whose behavior is affected by the interactions it has with processes found in other branches of the derivation. However, we can detect (some) unfair branches by looking at the non-deterministic choices they traverse, since choices are made autonomously by processes. To this aim, we introduce the notion of rank to estimate the least number of choices a process can possibly make during its lifetime.

**Definition 14 (rank).** Let \(r\) and \(s\) range over the elements of \(\mathbb{N}^\infty \equiv \mathbb{N} \cup \{\infty\}\) equipped with the expected total order \(\leq\) and operation \(+\) such that \(r + \infty = \infty + r = \infty\). The rank of a process \(P\), written \(|P|\), is the least element of \(\mathbb{N}^\infty\) such that

\[
\begin{align*}
|x \leftrightarrow y| &= 0 & |x(y, z).P| &= |P| & \text{case } x(y)\{P, Q\} &= \max\{|P|, |Q|\} \\
|\text{case } x(y)\{P, Q\}| &= 0 & |\text{in } \tau(y).P| &= |P| & |P \oplus Q| &= 1 + \min\{|P|, |Q|\} \\
|\tau| &= 0 & |\text{rec } \tau(y).P| &= |P| & |(x)(P || Q)| &= |P| + |Q| \\
|x().P| &= |P| & |\text{corec } x(y).P| &= |P| & |\tau(y, z)(P || Q)| &= |P| + |Q|
\end{align*}
\]

Roughly, the rank of terminated processes is 0, that of processes with a single continuation \(P\) coincides with the rank of \(P\), and that of processes spawning two continuations \(P\) and \(Q\) is the sum of the ranks of \(P\) and \(Q\). Then, the rank of a sum input with continuations \(P\) and \(Q\) is conservatively estimated as the maximum of the ranks of \(P\) and \(Q\), since we do not know which one will be taken, whereas the rank of a choice with continuations \(P\) and \(Q\) is 1 plus the minimum of the ranks of \(P\) and \(Q\). If we take Buyer and Seller from Example 2 we have \(|Buyer(x)| = 1\) and \(|Seller(x, y)| = 0\). We also have \(|\Omega(x)| = \infty\). Note that \(|P|\) only depends on the structure of \(P\) but not on the actual names occurring in \(P\), so it is well and uniquely defined as the least solution of a finite system of equations (see Appendix E.2).

**Definition 15.** A branch is fair if it traverses finitely many, finitely-ranked choices.

A finitely-ranked choice is at finite distance from a region of the process in which there are no more choices. An unfair branch gets close to such region infinitely often, but systematically avoids entering it. Note that every finite branch is also fair, but there are fair branches that are infinite. For instance, all the infinite branches of the derivation in Equation (1) and the only infinite branch in the derivation for Seller\((x, y)\) of Example 8 are fair since they do not traverse any finitely-ranked choice. On the contrary, the only infinite branch in the derivation for Buyer\((x)\) of the Example 8 is unfair since it traverses infinitely many finitely-ranked choices. All fair branches in the same derivation for Buyer are finite.

At last we can define our notion of well-typed process.

**Definition 16 (well-typed process).** We say that \(P\) is well typed in \(\Gamma\), written \(P \vdash \Gamma\), if the judgment \(P \vdash \Gamma\) is derivable and each fair, infinite branch in its derivation is valid.
Note that $\Omega$ is ill typed since the fair, infinite branches in Equation (1) are all invalid. We can now formulate the key properties of well-typed processes, starting from subject reduction.

**Theorem 17** (subject reduction). If $P \vdash \Gamma$ and $P \Rightarrow Q$ then $Q \vdash \Gamma$.

All reductions in Table 2 except those for non-deterministic choices correspond to cut-elimination steps in a quasi typing derivation. As an illustration, below is a fragment of the derivation tree for two processes exchanging a pair of $y$ and $z$ on channel $x$.

$$
\begin{array}{ll}
  P \vdash \Gamma, y : S & Q \vdash \Delta, z : T \\
  \pi(y, z)(P \parallel Q) \vdash \Gamma, \Delta, x : S \otimes T & x(y, z).R \vdash \Gamma', x : S^+ \otimes T^+ \\
  (x)(\pi(y, z)(P \parallel Q) \parallel x(y, z).R) \vdash \Gamma, \Delta, \Gamma'
\end{array}
$$

As the process reduces, the quasi typing derivation is rearranged so that the cut on $x$ is replaced by two cuts on $y$ and $z$. The resulting quasi typing derivation is shown below.

$$
\begin{array}{ll}
  P \vdash \Gamma, y : S & Q \vdash \Delta, z : T \\
  (z)(Q \parallel R) \vdash \Delta, \Gamma', y : S^+ \\
  (y)(P \parallel (z)(Q \parallel R)) \vdash \Gamma, \Delta, \Gamma'
\end{array}
$$

It is also interesting to observe that, when $P \Rightarrow Q$, the reduct $Q$ is well typed in the same context as $P$ but its rank may be different. In particular, the rank of $Q$ can be greater than the rank of $P$. Recalling that the rank of a process estimates the number of choices that the process must perform to terminate, the fact that the rank of $Q$ increases means that $Q$ moves away from termination instead of getting closer to it (we will see an instance where this phenomenon occurs in Example 23). What really matters is that a well-typed process is weakly terminating. This is the second key property ensured by our type system.

**Lemma 18** (weak termination). If $P \vdash x : 1$ then $P \Rightarrow \bot$.

The proof of Lemma 18 is a refinement of the cut elimination property of $\mu\text{MALL}^\infty$. Essentially, the only new case we have to handle is when a choice $P_1 \oplus P_2$ “emerges” towards the bottom of the typing derivation, meaning that it is no longer guarded by any action. In this case, we reduce the choice to the $P_1$ with smaller rank, which is guaranteed to lay on a fair branch of the derivation. An auxiliary result used in the proof of Lemma 18 is that our type system is a conservative extension of $\mu\text{MALL}^\infty$.

**Lemma 19.** If $P \vdash x_1 : S_1, \ldots, x_n : S_n$ then $\vdash S_1, \ldots, S_n$ is derivable in $\mu\text{MALL}^\infty$.

The property that well-typed processes can always successfully terminate is a simple consequence of Theorem 17 and Lemma 18.

**Theorem 20** (soundness). If $P \vdash x : 1$ and $P \Rightarrow Q$ then $Q \Rightarrow \pi()$.

Theorem 20 entails all the good properties we expect from well-typed processes: failure freedom (no unguarded sub-process case $y()$ ever appears), deadlock freedom (if the process stops it is terminated), lock freedom [26, 33] (every pending action can be completed in finite time) and junk freedom (every channel can be depleted). The combination of Theorems 5 and 20 also guarantees the termination of every fair run of the process.

**Corollary 21** (fair termination). If $P \vdash x : 1$ then $P$ is fairly terminating.
Observe that zero-ranked process do not contain any non-deterministic choice. In that case, every infinite branch in their typing derivation is fair and our validity condition coincides with that of \(\mu\text{MALL}^\infty\). As a consequence, we obtain the following strengthening of Corollary \ref{corollary:termination}

\begin{prop}
If \(P \vdash x : 1\) and \(|P| = 0\) then \(P\) is terminating.
\end{prop}

For regular processes (those consisting of finitely many distinct sub-trees, up to renaming of bound names) it is possible to easily adapt the algorithm that decides the validity of a \(\mu\text{MALL}^\infty\) proof so that it decides the validity of a \(\pi\text{LIN}\) typing derivation. The algorithm is sketched in more detail in Appendix \ref{appendix:algorithm}.

\begin{exmp}[parallel programming] In this example we see a \(\pi\text{LIN}\) modeling of a parallel programming pattern whereby a Work process creates an unbounded number of workers each one dedicated to an independent task and a Gather process collects and combines the partial results from the workers. The processes Work and Gather are defined as follows:

\[
\begin{align*}
\text{Work}(x) &= \text{rec } \pi. (\text{complex } \pi \pi(y) (\pi) \parallel \text{Work}(x)) \oplus \text{simple } \pi \pi()) \\
\text{Gather}(x, z) &= \text{corec } x. \text{case } x \{ x(y). y(). \text{Gather}(x, z), x(). \pi() \}
\end{align*}
\]

At each iteration, the Work process non-deterministically decides whether the task is complex (left hand side of the choice) or simple (right hand side of the choice). In the first case, it bifurcates into a new worker, which in the example simply sends a unit on \(y\), and another instance of itself. In the second case it terminates. The Gather process joins the results from all the workers before signalling its own termination by sending a unit on \(z\).

Note that the number of actions Gather has to perform before terminating is unbounded, as it depends on the non-deterministic choices made by Work.

Below is a typing derivation for Work where \(\varphi \equiv \mu X. (1 \otimes X) \oplus 1\) and \(a\) is an arbitrary atomic address:

\[
\begin{array}{c}
\vdash \pi() \vdash y : 1 \\
\pi(y) (\pi) \parallel \text{Work}(x) \vdash x : (1 \otimes \varphi)_{\text{alt}} \\
\text{complex } \pi \ldots \vdash x : ((1 \otimes \varphi) \oplus 1)_{\text{alt}} \\
\text{simple } \pi \pi() \vdash x : ((1 \otimes \varphi) \oplus 1)_{\text{alt}} \ \ \ \ \ \text{(replacement)}
\end{array}
\]

\[
\begin{array}{c}
\vdash \text{complex } \pi \pi(y) (\pi) \parallel \text{Work}(x) \oplus \text{simple } \pi \pi() \vdash x : ((1 \otimes \varphi) \oplus 1)_{\text{alt}} \\
\text{Work}(x) \vdash x : \varphi_{\alpha}
\end{array}
\]

Note that the only infinite branch in this derivation is unfair because it traverses infinitely many choices with rank \(1 = |\text{Work}(x)|\). So, Work is well typed.

Concerning Gather, we obtain the following typing derivation where \(\psi \equiv \nu X. (\bot \otimes X) \& \bot\):

\[
\begin{array}{c}
\vdash \text{Gather}(x, z) \vdash x : \psi_{\alpha + \delta t}, z : 1 \\
\vdash \pi() \vdash x : \psi_{\alpha + \delta t}, y : \bot, z : 1 \\
\vdash x(y). y(). \text{Gather}(x, z) \vdash x : (\bot \otimes \psi)_{\alpha + \delta t}, z : 1 \\
\text{case } x \{ x(y). y(). \text{Gather}(x, z), x(). \pi() \} \vdash x : ((\bot \otimes \psi) \& \bot)_{\alpha + \delta l}, z : 1 \\
\text{Gather}(x, z) \vdash x : \psi_{\alpha}, z : 1
\end{array}
\]

Here too there is just one infinite branch, which is fair and supported by the \(\nu\)-thread \(t = (\psi_{\alpha}, ((\bot \otimes \psi) \& \bot)_{\alpha + \delta l}, (\bot \otimes \psi)_{\alpha + \delta t}, \ldots)\). Indeed, all the formulas in \(\overline{\tau}\) occur
Fair Termination in the Linear $\pi$-Calculus

infinite often and $\min \inf (t) = \psi$ which is a $\nu$-formula. Hence, Gather is well typed and so is the composition $(x)(\text{Work}(x) \parallel \text{Gather}(x, z))$ in the context $z :: 1$. We conclude that the program is fairly terminating, despite the fact that the composition of Work and Gather may grow arbitrarily large because Work may spawn an unbounded number of workers. ■

- **Example 24** (forwarder). In this example we illustrate a deterministic, well-typed process that unfolds a least fixed point infinitely many times. In particular, we consider once again the formulas $\varphi \equiv \mu X . X \oplus 1$ and $\psi \equiv \nu X . X \& \bot$ and the process $Fwd$ defined by the equation

$$Fwd(x, y) = \text{corec } x . \text{rec } \overline{y} \text{. case } x \{ \text{in}_1 \overline{y} . Fwd(x, y), \text{in}_2 \overline{y}. x() \overline{y}() \}$$

which forwards the sequence of messages received from channel $x$ to channel $y$. We derive

<table>
<thead>
<tr>
<th>$Fwd(x, y) \vdash x : \psi_a alt, y : \varphi bi$</th>
<th>$x(). \overline{y}() \vdash x : \bot, y : 1$</th>
</tr>
</thead>
<tbody>
<tr>
<td>$\text{in}<em>1 \overline{y}. Fwd(x, y) \vdash x : \psi_a alt, y : (\varphi \oplus 1)</em>{bi}$</td>
<td>$\text{in}<em>2 \overline{y}. x(). \overline{y}() \vdash x : \bot, y : (\varphi \oplus 1)</em>{bi}$</td>
</tr>
<tr>
<td>$\text{case } x { \text{in}<em>1 \overline{y}. Fwd(x, y), \text{in}<em>2 \overline{y}. x(). \overline{y}() } \vdash x : (\psi &amp; \bot)</em>{alt}, y : (\varphi \oplus 1)</em>{bi}$</td>
<td>$Fwd(x, y) \vdash x : \psi_a, y : \varphi_b$</td>
</tr>
</tbody>
</table>

and observe that $|Fwd(x, y)| = 0$. This typing derivation is valid because the only infinite branch is fair and supported by the $\nu$-thread of $\psi_a$. Note that $\varphi = \psi^+$ and that the derivation proves an instance of $\Box\Box$. In general, the axiom is admissible in $\muMALL^\infty [4]$. ■

- **Example 25** (slot machine). Rank finiteness is not a necessary condition for well typedness. As an example, consider the system $(x)(\text{Player}(x) \parallel \text{Machine}(x, y))$ where

$$\text{Player}(x) = \text{rec } \overline{x}. (\text{play } \overline{x}. \text{case } x \{ \text{Player}(x), \text{rec } \overline{x}. \text{quit } \overline{x}. \overline{x}() \} \oplus \text{quit } \overline{x}. \overline{x}())$$

$$\text{Machine}(x, y) = \text{corec } x. \text{case } x \{ \text{win } \overline{x}. \text{Machine}(x, y) \oplus \text{lose } \overline{x}. \text{Machine}(x, y), x(). \overline{x}() \}$$

which models a game between a player and a slot machine. At each round, the player decides whether to play or to quit. In the first case, the slot machine answers with either win or lose. If the player wins, it also quits. Otherwise, it repeats the same behavior. It is possible to show that $\text{Player}(x) \vdash x : \varphi_a$, and $\text{Machine}(x, y) \vdash x : \psi_a alt, y : 1$ are derivable where $\varphi \equiv \mu X . (X \& X) \oplus 1$ and $\psi \equiv \nu X . (X \& Y) \& \bot$, see Appendix $F$ for the details. The only infinite branch in the derivation for $\text{Player}$ is unfair since $|\text{Player}(x)| = 1$, so $\text{Player}$ is well typed. There are infinitely many branches in the derivation for $\text{Machine}$ accounting for all the sequences of win and lose choices that can be made. Since $|\text{Machine}(x, y)| = \infty$, all these branches are fair but also valid. So, the system as a whole is well typed. ■

## 6 Related Work

On account of the known encodings of sessions into the linear $\pi$-calculus $[27][11][43]$, $\pi$LIN belongs to the family of process calculi providing logical foundations to sessions and session types. Some representatives of this family are $\piDILL [7]$ and its variant equipped with a circular proof theory $[13][43]$, CP $[43]$ and $\muCP [31]$, among others. There are two main aspects distinguishing $\pi$LIN from these calculi. The first one is that these calculi take sessions as a native feature. This fact can be appreciated both at the level of processes, where session endpoints are linearized resources that can be used multiple times albeit in a sequential way, and also at the level of types, where the interpretation of the $\varphi \otimes \psi$ and $\varphi \otimes \psi$ formulas is skewed so as to distinguish the type $\varphi$ of the message being sent/received on a channel...
from the type $\psi$ of the channel after the exchange has taken place. In contrast, $\pi\text{LIN}$ adopts a more fundamental communication model based on linear channels, and is thus closer to the spirit of the encoding of linear logic proofs into the $\pi$-calculus proposed by Bellin and Scott \cite{BS93} while retaining the same expressiveness of the aforementioned calculi. To some extent, $\pi\text{LIN}$ is also more general than those calculi, since a formula $\varphi \otimes \psi$ may be interpreted as a protocol that bifurcates into two independent sub-protocols $\varphi$ and $\psi$ (we have seen an instance of this pattern in Example 23). So, $\pi\text{LIN}$ is natively equipped with the capability of modeling some multiparty interactions, in addition to all of the binary ones. A session-based communication model identical to $\pi\text{LIN}$, but whose type system is based on intuitionistic rather than classical linear logic, has been presented by DeYoung et al. \cite{DNS17}. In that work, the authors advocate the use of explicit continuations with the purpose of modeling an asynchronous communication semantics and they prove the equivalence between such model and a buffered session semantics. However, they do not draw a connection between the proposed calculus and the linear $\pi$-calculus \cite{DS89} through the encoding of binary sessions \cite{DNS17} and, in the type system, the multiplicative connectives are still interpreted asymmetrically. The second aspect that distinguishes $\pi\text{LIN}$ from the other calculi is its type system, which is still deeply rooted into linear logic and yet it ensures fair termination instead of progress \cite{FCB99,BS93,P03}, termination \cite{AM04} or strong progress \cite{DF95,DF97}. Fair termination entails progress, strong progress and lock freedom \cite{FCB99,HS98}, but at the same time it does not always rule out processes admitting infinite executions. Simply, infinite executions are deemed unrealistic because they are unfair.

Another difference between $\pi\text{LIN}$ and other calculi based on linear logic is that its operational semantics is completely ordinary, in the sense that it does not include commuting conversions, reductions under prefixes, or the swapping of communication prefixes. The cut elimination result of $\mu\text{MALL}^\omega$, on which the proof of Theorem \ref{thm:cutelimination} is based, works by reducing cuts from the bottom of the derivation instead of from the top \cite{BC01,BL92}. As a consequence, it is not necessary to reduce cuts guarded by prefixes or to push cuts deep into the derivation tree to enable key reductions in $\pi\text{LIN}$ processes.

Some previous works \cite{BCF10,BF12} have studied type systems ensuring the fair termination of binary and multiparty sessions. Although the enforced property is the same and the communication models of these works are closely related to the one we consider here, the used techniques are quite different and the families of well-typed processes induced by the two type systems are not comparable. One aspect that is shared among all of these works, including the present one, is the use of a rank annotation or function that estimates how far a process is from termination. In previous works for session-based communications \cite{BCF10,BF12}, ranks account for the number of sessions that processes create and the number of times they use subtyping before they terminate. Since ranks are required to be finite, this means that deterministic processes can only create a finite number of sessions and can only use subtyping a finite number of times. As a consequence, the forwarder in Example \ref{ex:forwarder} is ill typed according to those typing disciplines because it applies subtyping (in an implicit way, whenever it sends a tag) an unbounded number of times. At the same time, a “compulsive” variant of the player in Example \ref{ex:compulsive} that keeps playing until it wins is well typed in previous type systems \cite{BCF10,BF12} but ill typed in the present one. This difference stems, at least in part, from the fact that the previous type systems support processes defined using general recursion, whereas $\pi\text{LIN}$’s type system relies on the duality between recursion and corecursion. A deeper understanding of these differences requires further investigation.

The extension of calculi based on linear logic with non-deterministic features has recently received quite a lot of attention. Rocha and Caires \cite{RC17} have proposed a session calculus with
shared cells and non-deterministic choices that can model mutable state. Their typing rule for non-deterministic choices is the same as our own, but in their calculus choices do not reduce. Rather, they keep track of every possible evolution of a process to be able to prove a confluence result. Qian et al. [37] introduce coexponentials, a new pair of modalities that enable the modeling of concurrent clients that compete in order to interact with a shared server that processes requests sequentially. In this setting, non-determinism arises from the unpredictable order in which different clients are served. Interestingly, the coexponentials are derived by resorting to their semantics in terms of least and greatest fixed points. For this reason, the cut elimination result of $\mu$MALL$^{\infty}$ might be useful to attack the termination proof in their setting.

7 Concluding Remarks

We have studied a conservative extension of $\mu$MALL$^{\infty}$ [1] [16] [3], an infinitary proof system of multiplicative additive linear logic with fixed points, that serves as type system for $\pi$LIN, a linear $\pi$-calculus with (co)recursive types. Well-typed processes fairly terminate.

One drawback of the proposed type system is that establishing whether a quasi-typed process is also well typed requires a global check on the whole typing derivation. The need for a global check seems to arise commonly in infinitary proof systems [12] [16] [4] [3], so an obvious aspect to investigate is whether the analysis can be localized. A possible source of inspiration for devising a local type system for $\pi$LIN might come from the work of Derakhshan and Pfenning [14]. They propose a compositional technique for dealing with infinitary typing derivations in a session calculus, although their type system is limited to the additive fragment of linear logic.

Fair subtyping [32] [34] is a refinement of the standard subtyping relation for session types [19] that preserves fair termination and that plays a key role in our previous type system ensuring fair termination for binary sessions [10]. Given the rich literature exploring the connections between linear logic and session types, $\pi$LIN and its type system might provide the right framework for investigating the logical foundations of fair subtyping.

16:18 Fair Termination in the Linear π-Calculus

A Properties of fair termination

A key property of any notion of fair run is that of feasibility [2] also known as machine closure [30], stating that every finite reduction may be extended to a fair run. It is not difficult to prove that this property is enjoyed by our notion of fair run.

Lemma 26 (feasibility). Let \( P \Rightarrow Q \) and \( (P_i)_{0 \leq i \leq n} \) be the sequence of processes visited by these reductions. Then there exists a run \( \rho \) of \( Q \) such that \( (P_i)_{0 \leq i < n} \rho \) is a fair run of \( P \).

Proof. Let \( (P_i)_{0 \leq i \leq n} \) be the sequence of processes visited by the reductions \( P \Rightarrow Q \), where \( P_0 = P \) and \( P_n = Q \). We distinguish two possibilities. If \( Q \) is weakly terminating, then there exists a finite run \( \rho \) of \( Q \). Then, \( (P_i)_{0 \leq i < n} \rho \) is a finite fair run of \( P \). If \( Q \) is not weakly terminating, then \( Q \) has at least one infinite run \( \rho \) in which no process is weakly terminating. Then \( (P_i)_{0 \leq i < n} \rho \) is an infinite fair run of \( P \).

Theorem 5 (proof principle for fair termination). \( P \) is fairly terminating if and only if \( P \Rightarrow Q \) implies that \( Q \) is weakly terminating.

Proof. \((\Rightarrow)\) Let \( P_0 \cdots P_n \) be the sequence of processes visited by the reductions \( P \Rightarrow Q \). By Lemma 26, we deduce that there exists a run \( \rho \) of \( Q \) such that \( P_0 \cdots P_n \rho \) is a fair run \( \rho \) of \( P \). From the hypothesis that \( P \) is fairly terminating we deduce that \( \rho \) is finite. That is, \( Q \) is weakly terminating.

\((\Leftarrow)\) Let \( \rho \) be a fair run of \( P \) and suppose that it is infinite. Then there exists some \( Q \) in this run such that \( P \Rightarrow Q \) and \( Q \) is not weakly terminating, which contradicts the hypothesis.

B Proof of Theorem 17

Lemma 27 (substitution). If \( P \vdash \Gamma, x : S \) and \( y \notin \text{dom}(\Gamma) \), then \( P[y/x] \vdash \Gamma, y : S \).

Proof. A simple application of the coinduction principle.

Lemma 28 (quasi subject congruence). If \( P \vdash \Gamma \) and \( P \not\preceq Q \), then \( Q \not\vdash \Gamma \).

Proof. By induction on the derivation of \( P \not\preceq Q \) and by cases on the last rule applied. We only discuss the base cases.
16:20 Fair Termination in the Linear $\pi$-Calculus

Case [s-link] Then $P = x \leftrightarrow y \not\equiv y \leftrightarrow x = Q$. From $[\text{AX}]$ we deduce that there exist $\varphi$, $\alpha$ and $\beta$ such that $\Gamma = x : \varphi_\alpha, y : \varphi_\beta^+$. We conclude with an application of $[\text{AX}].$

Case [s-comm] Then $P = (x)(P_1 \parallel P_2) \not\equiv (x)(P_2 \parallel P_1) = Q$. From $[\text{cut}]$ we deduce that there exist $\Gamma_1$, $\Gamma_2$, and $S$ such that

\begin{align*}
\Gamma &= \Gamma_1, \Gamma_2 \\
S_1 &= P_1 \vdash \Gamma_1, x : S \\
S_2 &= P_2 \vdash \Gamma_2, x : S^+ \\
\text{We conclude with an application of } \text{[cut].}
\end{align*}

Case [s-assoc] Then $P = (x)(P_1 \parallel (y)(P_2 \parallel P_3)) \not\equiv (y)((x)(P_1 \parallel P_2) \parallel P_3) = Q$ and $x \in \text{fn}(P_2)$. From $[\text{cut}]$ we deduce that there exist $\Gamma_1$, $\Gamma_2$, $\Gamma_3$, $S$, $T$ such that

\begin{align*}
\Gamma &= \Gamma_1, \Gamma_2, \Gamma_3 \\
S_1 &= P_1 \vdash \Gamma_1, x : S \\
S_2 &= P_2 \vdash \Gamma_2, x : S^+, y : T \\
S_3 &= P_3 \vdash \Gamma_3, y : T^+ \\
\text{We conclude with two applications of } \text{[cut].}
\end{align*}

$\blacktriangleright$ Lemma 29 (quasi subject reduction). If $P \rightarrow Q$ then $P \vdash \Gamma$ implies $Q \vdash \Gamma$.

Proof. By induction on $P \rightarrow Q$ and by cases on the last rule applied.

Case [r-link] Then $P = (x)(x \leftrightarrow y \parallel R) \rightarrow R\{y/x\} = Q$. From $[\text{cut}]$ and $[\text{AX}]$ we deduce that there exist $\varphi_\alpha$, $\varphi_\beta$ and $\Delta$ such that $\Gamma = y : \varphi_\beta^+, \Delta$ and $R \vdash \Delta, x : \varphi_\beta^+$. We conclude by applying Lemma 27.

Case [r-unit] Then $P = (x)(\pi(\cdot) \circ x).Q) \rightarrow Q$. From $[\text{cut}]$, $[1]$, and $[4]$ we conclude $Q \vdash \Gamma$.

Case [r-fair] Then $P = (x)(\pi(y,z)(x)(P_1 \parallel P_2) \parallel (y,z).P_3) \rightarrow (y)(P_1 \parallel (P_2 \parallel P_3)) = Q$. From $[\text{cut}]$, $[2]$, and $[8]$ we deduce that there exist $\Gamma_1$, $\Gamma_2$, $\Gamma_3$, $S$ and $T$ such that

\begin{align*}
\Gamma &= \Gamma_1, \Gamma_2, \Gamma_3 \\
S_1 &= P_1 \vdash \Gamma_1, y : S \\
S_2 &= P_2 \vdash \Gamma_2, z : T \\
S_3 &= P_3 \vdash \Gamma_3, y : S^+, z : T^+ \\
\text{We conclude with two applications of } \text{[cut].}
\end{align*}

Case [r-sum] Then $P = (x)(\text{in}_{i}(y).R \parallel \text{case } x(y)(P_1, P_2)) \rightarrow (y)(R \parallel P_1) = Q$ for some $i \in \{1, 2\}$. From $[\text{cut}]$, $[5]$, and $[9]$ we deduce that there exist $\Gamma_1$, $\Gamma_2$, $S_1$ and $S_2$ such that

\begin{align*}
\Gamma &= \Gamma_1, \Delta \\
R &\vdash \Gamma_1, y : S_i \\
S_1 &= P_1 \vdash \Gamma_2, y : S_1^+ \\
S_2 &= P_2 \vdash \Gamma_2, y : S_2^+ \\
\text{We conclude with an application of } \text{[cut].}
\end{align*}

Case [r-rec] Then $P = (x)(\text{rec } \pi(y).P_1 \parallel \text{corec } x(y).P_2) \rightarrow (y)(P_1 \parallel P_2) = Q$. From $[\text{cut}]$, $[\mu]$ and $[7]$ we deduce that there exist $\Gamma_1$, $\Gamma_2$ and $S$ such that

\begin{align*}
\Gamma &= \Gamma_1, \Gamma_2 \\
P_1 &\vdash \Gamma_1, y : S\{\mu X.S/X\} \\
P_2 &\vdash \Gamma_2, y : S^+\{\nu X.S^+/X\} \\
\text{We conclude with an application of } \text{[cut].}
\end{align*}

Case [r-choice] Then $P = P_1 \parallel P_2 \rightarrow P_i = Q$ for some $i \in \{1, 2\}$. From $[\text{choice}]$ we conclude that $P_i \vdash \Gamma$.

Case [r-cut] Then $P = (x)(P' \parallel R) \rightarrow (x)(Q' \parallel R) = Q$ and $P' \rightarrow Q'$. From $[\text{cut}]$ we deduce that there exist $\Gamma_1$, $\Gamma_2$ and $S$ such that

\begin{align*}
\Gamma &= \Gamma_1, \Gamma_2
\end{align*}
Using the induction hypothesis on \( P' \rightarrow Q' \) we deduce \( Q' \vdash \Gamma_1 \), \( x : S \). We conclude with an application of \( \text{cut} \).

**Case \( \text{r-struct} \)**. Then \( P \ll R \rightarrow Q \) for some \( R \). From Lemma 28 we deduce \( R \vdash \Gamma \). Using the induction hypothesis on \( R \rightarrow Q \) we conclude \( Q \vdash \Gamma \).

\[ \triangleright \]

**Theorem 17** (subject reduction). If \( P \vdash \Gamma \) and \( P \rightarrow Q \) then \( Q \vdash \Gamma \).

**Proof.** From the hypothesis \( P \vdash \Gamma \) we deduce \( P \vdash \Gamma \). Using Lemma 29 we deduce \( Q \vdash \Gamma \). Now, let \( \gamma \) be an infinite fair branch in the typing derivation for \( Q \vdash \Gamma \). By inspecting the proof of Lemma 29 we observe that \( \gamma \) can be decomposed as \( \gamma = \gamma_1 \gamma_2 \) where \( \gamma_2 \) is a branch in the typing derivation for \( Q \vdash \Gamma \). From the fact that \( \gamma \) is fair we deduce that so is \( \gamma_2 \). From the hypothesis \( P \vdash \Gamma \) we deduce that \( \gamma_2 \) is valid, namely there is a \( \nu \)-thread \( t \) in it. Then \( t \) is a \( \nu \)-thread also of \( \gamma \), that is \( \gamma \) is also valid. We conclude \( Q \vdash \Gamma \).

\[ \triangleright \]

### C Soundness of the Type System

#### C.1 Proximity Lemma and Multicuts

The cut elimination result of \( \mu \text{MALL}^\infty \) is proved by introducing a multicut rule that collapses several unguarded cuts in a single rule having a variable number of premises. The usefulness of working with multicuts is that they prevent infinite sequences of reductions where two cuts are continuously permuted in a non-productive way and no real progress is made in the cut elimination process. In the type system of \( \pi \text{LIN} \) we do not have a typing rule corresponding to the multicut. At the same time, the troublesome permutations of cut rules correspond to applications of the associativity law of parallel composition, namely of the \( \text{[s-assoc]} \) pre-congruence rule. That is, the introduction of the multicut rule in the cut elimination proof of \( \mu \text{MALL}^\infty \) corresponds to working with \( \pi \text{LIN} \) terms considered equal up to structural pre-congruence. Nonetheless, since the \( \pi \text{LIN} \) reduction rules require two processes willing to interact on some channel \( x \) to be the children of the same application of \( \text{cut} \) it is not entirely obvious that not introducing an explicit multicut rule allows us to perform in \( \pi \text{LIN} \) all the principal reductions that are performed during the cut elimination process in a \( \mu \text{MALL}^\infty \) proof.

Here we show that this is actually the case by proving a so-called proximity lemma, showing that every well-typed process can be rewritten in a structurally pre-congruent one where any two processes in which the same channel \( x \) occurs free are the children of a cut on \( x \). To this aim, we introduce process contexts to refer to unguarded sub-terms of a process. Process contexts are processes with a single unguarded hole \([ \cdot ]\) and are generated by the following grammar:

\[
\text{Process context } \quad \mathcal{C}, \mathcal{D} \quad ::= \quad [ \cdot ] \quad | \quad (x)(\mathcal{C} \parallel P) \quad | \quad (x)(P \parallel \mathcal{C})
\]

As usual we write \( \mathcal{C}[P] \) for the process obtained by replacing the hole in \( \mathcal{C} \) with \( P \). Note that this substitution is not capture-avoiding in general and some free names occurring in \( P \) may be captured by binders in \( \mathcal{C} \). We write \( \text{bn}(\cdot) \) for the function inductively defined by

\[
\text{bn}( [ \cdot ] ) = \emptyset \quad \text{and} \quad \text{bn}( (x)(\mathcal{C} \parallel P) ) = \text{bn}( (x)(P \parallel \mathcal{C}) ) = \{ x \} \cup \text{bn}(\mathcal{C})
\]

The next lemma shows that a cut on \( x \) can always be pushed down towards any process in which \( x \) occurs free.
Lemma 30. If \( x \in \text{fn}(P) \setminus \text{bn}(C) \), then \( (x)(C[P] \parallel Q) \equiv D[(x)(P \parallel Q)] \) for some \( D \).

Proof. By induction on the structure of \( C \) and by cases on its shape.

Case \( C = [ ] \). We conclude by taking \( D \equiv [ ] \) using the reflexivity of \( \equiv \).

Case \( C = (y)(C' \parallel R) \). From the hypothesis \( x \in \text{fn}(P) \setminus \text{bn}(C) \) we deduce \( x \neq y \) and \( x \in \text{fn}(P) \setminus \text{bn}(C') \). Using the induction hypothesis we deduce that there exists \( D' \) such that \( (x)(C'[P] \parallel Q) \equiv D'[(x)(P \parallel Q)] \). Take \( D \equiv (y)(D' \parallel R) \). We conclude

\[
(x)(C'[P] \parallel Q) = (x)((y)(C'[P] \parallel R) \parallel Q) \text{ by definition of } C
\]

\[
\approx (x)(Q \parallel (y)(C'[P] \parallel R)) \text{ by } [\text{s-comm}]
\]

\[
\approx (y)((x)(Q \parallel C'[P]) \parallel R) \text{ from } x \in \text{fn}(P) \setminus \text{bn}(C) \text{ and } [\text{s-comm}]
\]

\[
\approx (y)((x)(C'[P] \parallel Q) \parallel R) \text{ by } [\text{s-comm}]
\]

\[
\approx (y)(D'[(x)(P \parallel Q)] \parallel R) \text{ using the induction hypothesis}
\]

\[
= D[(x)(P \parallel Q)] \text{ by definition of } D
\]

Case \( C = (y)(R \parallel C') \). Analogous to the previous case.

The proximity lemma is then proved by applying Lemma 30 twice.

Lemma 31 (proximity). If \( x \in \text{fn}(P_i) \setminus \text{bn}(C_i) \) for \( i = 1, 2 \), then \( C[(x)(C_1[P_1] \parallel C_2[P_2]) \equiv D[(x)(P_1 \parallel P_2)] \) for some \( D \).

Proof. It suffices to apply Lemma 30 twice, thus:

\[
C[(x)(C_1[P_1] \parallel C_2[P_2])] \equiv C[D_1[(x)(P_1 \parallel C_2[P_2])]] \text{ using the hypothesis and Lemma 30}
\]

\[
\approx C[D_1[(x)(C_2[P_2] \parallel P_1)]] \text{ by } [\text{s-assoc}]
\]

\[
\approx C[D_1[D_2[(x)(P_2 \parallel P_1)]]] \text{ using the hypothesis and Lemma 30}
\]

\[
\approx C[D_1[D_2[(x)(P_1 \parallel P_2)]]] \text{ by } [\text{s-assoc}]
\]

and we conclude by taking \( D \equiv C[D_1[D_2]] \).

C.2 Auxiliary Properties of Well-Typed Processes

Most of the soundness proof of the type system relies on the cut elimination result of \( \mu\text{MALL}^\infty \). Here we gather some auxiliary definitions and properties of well-typed processes. First of all, we define a function that makes a “fair choice” among two processes \( P \) and \( Q \), by selecting the one with smaller rank. If \( P \) and \( Q \) happen to have the same rank, we choose \( P \) by convention.

Definition 32. The fair choice among \( P \) and \( Q \), written \( \text{fc}(P, Q) \), is defined by

\[
\text{fc}(P, Q) \equiv \begin{cases} P & \text{if } |P| \leq |Q| \\ Q & \text{otherwise} \end{cases}
\]

From its definition we have \( |\text{fc}(P, Q)| = \min\{|P|, |Q|\} \). Next, we show that in a well-typed process there cannot be an infinite sequence of choices if we follow the fair ones. To this aim, we define a total function on processes that computes the length of the longest chain of subsequent fair choices.

Definition 33. Let \( \text{depth}(\cdot) \) be the function from processes to \( \mathbb{N}^\infty \) such that

\[
\text{depth}(P) = \begin{cases} 1 + \text{depth}(\text{fc}(P_1, P_2)) & \text{if } P = P_1 \oplus P_2 \\ 0 & \text{otherwise} \end{cases}
\]
Note that \( \text{depth}(\text{fc}(P, Q)) < 1 + \text{depth}(\text{fc}(P, Q)) = \text{depth}(P \oplus Q) \). We prove that, for well-typed processes, \( \text{depth}(\cdot) \) always yields a natural number. That is, in a well-typed process there is no infinite chain of fair choices.

\begin{lemma}
If \( P \vdash \Gamma \) then \( \text{depth}(P) \in \mathbb{N} \).
\end{lemma}

\textbf{Proof.} Suppose that \( \text{depth}(P) = \infty \). Then the derivation for \( P \vdash \Gamma \) has an infinite branch 
\( \gamma = (P_i \vdash \Gamma)_{i \in \omega} \) solely consisting of choices such that \( |P_{i+1}| < |P_i| \) for every \( i \in \omega \). Therefore, \( |P_i| = \infty \) for every \( i \in \omega \) and \( \gamma \) is fair. From the hypothesis that \( P \) is well typed we deduce that \( \gamma \) is also valid (Definition 13), namely it has a non-stationary \( \nu \)-thread. This contradicts the fact that the contexts in \( \gamma \) are all equal to \( \Gamma \). We conclude that \( \text{depth}(P) \in \mathbb{N} \).

\begin{definition}
Let \( [\cdot] \) be the function on well-typed processes such that \( [P \oplus Q] = [\text{fc}(P, Q)] \) and extended homomorphically to all the other process forms.
\end{definition}

The fact that \( [P] \) is uniquely defined when \( P \) is well typed is a consequence of Lemma 34. Indeed, any branch of \( P \) that contains infinitely many choices also contains infinitely many forms other than choices. Note that the range of \( [\cdot] \) only contains zero-ranked processes.

The next two results prove that \( [P] \) is well typed if so is \( P \).

\begin{lemma}
If \( P \vdash \Gamma \) then \( [P] \vdash \Gamma \).
\end{lemma}

\textbf{Proof.} We apply the coinduction principle to show that every judgment in the set
\[ R \overset{\Delta}{=} \{ [P] \vdash \Gamma \mid P \vdash \Gamma \} \]
is the conclusion of a rule in Table 3 whose premises are also in \( R \). Let \( Q \vdash \Gamma \in R \). Then \( Q = [P] \) for some \( P \) such that \( P \vdash \Gamma \). From Lemma 34 we deduce that \( \text{depth}(P) \in \mathbb{N} \). We reason by induction on \( \text{depth}(P) \) and by cases on the shape of \( P \) to show that \( Q \vdash \Gamma \) is the conclusion of a rule in Table 3 whose premises are also in \( R \). We only discuss a few cases, the others being similar or simpler.

\textbf{Case} \( P = (x)(P_1 \parallel P_2) \). Then \( Q = [P] = (\text{fc}(P_1)) \parallel [P_2] \). From \textbf{cut} we deduce that there exists \( \Gamma_1, \Gamma_2, S_1 \) and \( S_2 \) such that \( P_i \vdash \Gamma_i, x : S_i \) for \( i = 1, 2 \) and \( \Gamma = \Gamma_1 \parallel \Gamma_2 \) and \( S_1 = S_2^\parallel \). Then \( [P_i] \vdash \Gamma_i, x : S_i \in R \) by definition of \( R \) and we conclude observing that \( Q \vdash \Gamma \in R \) is the conclusion of \textbf{cut}.

\textbf{Case} \( P = P_1 \oplus P_2 \). Then \( Q = [P] = [\text{fc}(P_1, P_2)] \). From \textbf{choice} we deduce \( \text{fc}(P_1, P_2) \vdash \Gamma \).

Since \( \text{depth}(\text{fc}(P_1, P_2)) < \text{depth}(P) \in \mathbb{N} \), we conclude using the induction hypothesis.

\begin{lemma}
If \( P \vdash \Gamma \) then \([P] \vdash \Gamma\).
\end{lemma}

\textbf{Proof.} Using Lemma 36 we deduce \([P] \vdash \Gamma \). Now, consider an infinite branch \( \gamma \) in the derivation for \([P] \vdash \Gamma \) and observe that \( \gamma \) is necessarily fair, since it does not traverse any choice. The branch \( \gamma \) corresponds to another infinite branch \( \gamma' \) in the derivation for \( P \vdash \Gamma \) which always makes fair choices whenever it traverses a process of the form \( P_1 \parallel P_2 \). The only differences between \( \gamma \) and \( \gamma' \) are the judgments for the choices in \( P \) that have been resolved. Nonetheless, all of the contexts that occur in \( \gamma' \) also occur in \( \gamma \) because \textbf{choice} does not affect typing contexts. If \( \gamma' \) traverses infinitely many choices, then \( \gamma' \) traverses infinitely many processes with strictly decreasing ranks, which must all be \( \infty \). Therefore, \( \gamma' \) is fair. Since \( P \) is well typed we know that \( \gamma' \) is valid. Then, the \( \nu \)-thread that witnesses the validity of \( \gamma' \) corresponds to a \( \nu \)-thread that witnesses the validity of \( \gamma \). We conclude that \([P] \) is well typed.
Lemma 19. If \( P \vdash x_1 : S_1, \ldots, x_n : S_n \) then \( \vdash S_1, \ldots, S_n \) is derivable in \( \mu\text{MALL}^\infty \).

Proof. By Lemma 37 we deduce \([P] \vdash x_1 : S_1, \ldots, x_n : S_n\). Since \(|[P]| = 0\), there are no applications of \([\text{choice}]\) in the derivation for \([P] \vdash x_1 : S_1, \ldots, x_n : S_n\). That is, this derivation corresponds to a \( \mu\text{MALL}^\infty \) derivation and every infinite branch in it is fair. Since \([P]\) is well typed, we deduce that every infinite branch in this derivation is valid. That is, \( \vdash S_1, \ldots, S_n \) is derivable in \( \mu\text{MALL}^\infty \).

The key property of zero-ranked processes that are well typed in a context \( x : 1 \) is that they are weakly terminating and they eventually reduce to \( \pi() \).

Lemma 38. If \( P \vdash x : 1 \) and \( |P| = 0 \) then \( P \Rightarrow \pi() \).

Proof. Without loss of generality we may assume that \( P \) does not contain links. Indeed, the axiom \([\text{ax}]\) is admissible in \( \mu\text{MALL}^\infty \) [4, Proposition 10], so we may assume that links have been expanded into equivalent (choice-free) processes. We just note that, if the statement holds for link-free processes, then it holds also in the case \( P \) does contain links, the only difference being that the sequence of reductions that are needed to fully eliminate all the cuts resulting from an expanded link are replaced by a single occurrence of \([\text{R-link}]\).

From the hypothesis that \( P \) has rank 0 we deduce that \( P \) does not contain non-deterministic choices and the derivation of \( P \vdash x : 1 \) does not contain applications of the \([\text{choice}]\) rule. So, every infinite branch of this derivation is fair. From the hypothesis that every infinite fair branch of this derivation is valid we deduce that every infinite branch of this derivation is valid. Then this derivation corresponds to a \( \mu\text{MALL}^\infty \) proof of \( \vdash 1 \).

Observe that every principal reduction rule of \( \mu\text{MALL}^\infty \) [16, Figure 3.2] corresponds to a reduction rule of \( \pi\text{LIN} \) (Table 2). Also, Lemma 31 guarantees that, whenever there are two processes in which the same channel name \( x \) occurs free we are always able to rewrite the process using structural precongruence so that the two sub-processes are the children of a cut on \( x \). Finally, the cut elimination result for \( \mu\text{MALL}^\infty \) is proved by reducing bottom-most cuts, meaning that principal reductions (also called internal reductions [10]) are only applied at the bottom of a \( \mu\text{MALL}^\infty \) proof. Therefore, each step in which a principal reduction is applied in the cut elimination result of \( \mu\text{MALL}^\infty \) can be mimicked by a reduction of \( \pi\text{LIN} \).

From the cut elimination result for \( \mu\text{MALL}^\infty \) [16, Proposition 3.5] we deduce that there exists no (fair) infinite sequence of principal reductions. That is, there exists a stuck \( Q \) such that \( P \Rightarrow Q \). From Lemma 29 we deduce \( Q \vdash x : 1 \). Since the only cut-free \( \mu\text{MALL}^\infty \) proof of \( \vdash 1 \) consists of a single application of \([\text{choice}]\) and since this proof corresponds to the proof that \( Q \) is quasi typed, we conclude that \( Q = \pi() \).

C.3 Proof of Theorem 20

The last auxiliary result for proving Lemma 18 is to show that \( P \) weakly simulates \([P]\), namely that every reduction of a process \([P]\) can be mimicked by one or more reductions of \( P \).

Lemma 39. If \( P \vdash \Gamma \) and \( [P] \Rightarrow Q \) then \( P \Rightarrow R \) for some \( R \) such that \( Q = [R] \).

Proof. From Lemma 34 we deduce \( \text{depth}(P) \in \mathbb{N} \). We proceed by double induction on \( \text{depth}(P) \) and on the derivation of \([P] \Rightarrow Q\) and by cases on the last rule applied in the derivation of \( P \vdash \Gamma \). Most cases are straightforward since the structure of \([P]\) and that of \( P \) only differ for non-deterministic choices, so we only discuss the case \([\text{choice}]\) in which \( P = P_1 \oplus P_2 \). Then \( \text{fc}(P_1, P_2) \vdash \Gamma \) and \([P] = [\text{fc}(P_1, P_2)] \Rightarrow Q \). Recall that
Lemma 39 can be easily generalized to arbitrary sequences of reductions.

Lemma 40. If \( P \vdash \Gamma \) and \( [P] \Rightarrow Q \) then \( P \Rightarrow R \) for some \( R \) such that \( Q = [R] \).

Proof. A simple induction on the number of reductions in \( [P] \Rightarrow Q \) using Lemma 39.

Lemma 18 (weak termination). If \( P \vdash x : 1 \) then \( P \Rightarrow \tau() \).

Proof. Using Lemma 37 we deduce \( [P] \vdash x : 1 \). Using Lemma 38 we deduce \( [P] \Rightarrow \tau() \). Using Lemma 40 and Lemma 29 we conclude \( P \Rightarrow \tau() \).

Theorem 20 (soundness). If \( P \vdash x : 1 \) and \( P \Rightarrow Q \) then \( Q \Rightarrow \tau() \).

Proof. By induction on the number of reductions in \( P \Rightarrow Q \), from the hypothesis \( P \vdash x : 1 \) and Theorem 17 we deduce \( Q \vdash x : 1 \). We conclude using Lemma 18.

Corollary 21 (fair termination). If \( P \vdash x : 1 \) then \( P \) is fairly terminating.

Proof. Immediate consequence of Theorems 5 and 20.

D Decidability of Proof Validity

In this section we sketch an algorithm for deciding our notion of proof validity (Definition 16). Clearly, this result holds assuming that the typing derivation for a given process is “sufficiently regular”, namely that it is representable as a circular derivation consisting of finitely many distinct sub-trees. This requires the introduction of a renaming rule [16] to account for the fact that addresses in types increase monotonically as they are unfolded along branches of a derivation. In this case, the decidability of the standard validity condition for \( \mu \text{MALL}^\infty \) has been established by Doumane [16, Chapter 2]. The algorithm relies on two word automata, a Büchi automaton \( M \) that accepts all the infinite branches in the graph representing the circular proof, and a parity automaton \( N \) accepting only the valid ones. The validity of the proof is then reduced to checking that \( L(M) \subseteq L(N) \). The difference between valid \( \mu \text{MALL}^\infty \) proofs and valid \( \pi \text{LIN} \) derivations is that we only want to check this inclusion considering the fair branches in a \( \pi \text{LIN} \) derivation, so decidability boils down to the ability of recognizing these branches. Considering that the fair branches are those that traverse finitely-ranked choices finitely many times, we build a Büchi automaton \( U \) accepting all the unfair branches, those that traverse finitely-ranked choices infinitely many times. The construction of \( U \) is analogous to that of \( M \) [16], with the difference that the set of accepting states coincides with the set of finitely-ranked choices. From \( M \) and \( U \) and the fact that \( \omega \)-regular languages are closed by complementation and intersection it is now possible to construct a Büchi automaton that accepts \( L(M) \setminus L(U) \). This language consists of all the infinite, fair branches. Now, the validity of the \( \pi \text{LIN} \) derivation boils down to checking the inclusion \( (L(M) \setminus L(U)) \subseteq L(N) \), which is a decidable problem.
E Supplement to Section 2

E.1 Finite Representation of Regular Processes

An alternative, possibly more conventional way of representing infinite but regular processes consists of considering the form \( A(x_1, \ldots, x_n) \) as being part of the syntax of processes. Then, one adds a structural precongruence rule \([s\mbox{-}\text{CALL}]\) such that

\[
A(x_1, \ldots, x_n) \preceq P \quad \text{if} \quad A(x_1, \ldots, x_n) = P
\]

so that occurrences of \( A(x_1, \ldots, x_n) \) can be unfolded into their definition. The typing rule for regular processes is the following:

\[
\frac{P \vdash x_1 : S_1, \ldots, x_n : S_n}{A(x_1, \ldots, x_n) \vdash x_1 : S_1, \ldots, x_n : S_n}\ \ [\text{CALL}]
\]

With these changes, the only difference in the presented results concerns the formulation of Theorem 20, since a process \( A(x) \) when \( A(x) = \pi() \) does not reduce and yet it is not syntactically equal to \( \pi() \). The solution is to slightly weaken the statement of the theorem allowing the use of structural pre-congruence for rewriting the final state of \( Q \):

\[\blacktriangleright \text{Theorem 41.} \quad \text{If} \ P \vdash x : 1 \ \text{and} \ P \Rightarrow Q \ \text{then} \ Q \Rightarrow \preceq \pi().\]

E.2 On the Definition of Rank

Here we provide a more detailed justification of the fact that the notion of rank (Definition 14) is well defined. As we have already observed, the value of \(|P|\) only depends on the structure of \( P \), but not on the actual names occurring in \( P \). As a consequence, when \( P \) is defined by means of a finite system of equations, the value of \(|P|\) too can be determined by a finite system of equations, even though \( P \) is not a regular tree strictly speaking.

As an example, consider the definition of \( \text{Buyer} \) found in Example 2. In order to compute \(|\text{Buyer}(x)|\) we consider the system of equations

\[
\begin{align*}
|\text{Buyer}(\bullet)| &= |\text{add } \bullet. \text{Buyer}(\bullet) \oplus \text{pay } \bullet. \text{\texttt{\pi}}()| \\
|\text{add } \bullet. \text{Buyer}(\bullet) \oplus \text{pay } \bullet. \text{\texttt{\pi}}()| &= 1 + \min\{|\text{add } \bullet. \text{Buyer}(\bullet)|, |\text{pay } \bullet. \text{\texttt{\pi}}()|\} \\
|\text{add } \bullet. \text{Buyer}(\bullet)| &= |\text{Buyer}(\bullet)| \\
|\text{pay } \bullet. \text{\texttt{\pi}}()| &= |\text{\texttt{\pi}}()| \\
|\text{\texttt{\pi}}()| &= 0
\end{align*}
\]

where we have used a placeholder \( \bullet \) in place of every channel name occurring in these terms.

Every such system of equations can be thought of as a function \( F : (\mathbb{N}^\infty)^n \rightarrow (\mathbb{N}^\infty)^n \) on the complete lattice \((\mathbb{N}^\infty)^n\) ordered by the pointwise extension of \( \leq \) in \( \mathbb{N}^\infty \). Note that \( F \) is monotone, because all the operators occurring in the definition of rank (Definition 14) are monotone. So, \( F \) has a least fixed point by the Knaster-Tarski theorem and the rank of \( P \) is the component of this fixed point that corresponds to \(|P|\).

For the above system of equations we have \( n = 5 \) and we have

\[
F(x_1, x_2, x_3, x_4, x_5) = (x_2, 1 + \min\{x_3, x_4\}, x_1, x_5, 0)
\]

whose least solution is \((1, 1, 1, 0, 0)\). Now \(|\text{Buyer}(x)|\) corresponds to the first component of this solution, that is 1.
Typing Derivations for Example 25

Below is the typing derivation showing that Player is quasi typed. For convenience, we define $\psi' \equiv (\psi \land \psi) \lor \bot$. Note that $\psi'$ is the unfolding of $\psi$ defined in Example 25.

$$\frac{\text{Player}(x) \vdash x : \psi_{alt}}{\text{case } x \{ \text{Player}(x), \text{rec } \varpi \text{. quit } \varpi(x) \} \vdash x : (\psi \land \psi)_{alt}}$$

Below is the typing derivation showing that Machine is quasi typed. For convenience, we define $\psi' \equiv \psi \lor \psi$ and we abbreviate Machine to $M$.

$$\frac{\text{win } \varpi.M(x, y) \vdash x : \psi_{bit}, y : 1 \quad \text{lose } \varpi.M(x, y) \vdash x : \psi_{bit}', y : 1 \quad \varpi(y) \vdash y : 1}{{\text{case } x \{ \text{win } \varpi.M(x, y) \lor \text{lose } \varpi.M(x, y), x() . \varpi(y) \} \vdash x : (\psi' \lor \bot)_{alt}, y : 1}}$$

Encoding of a Context-Free Protocol

In this appendix we illustrate the encoding of a context-free communication protocol in πLIN.

A context-free protocol (or session type) cannot be described accurately by plain session types in which recursion is allowed in tail position only. A paradigmatic example of such a protocol is that describing the (de)serialization of a binary tree \cite{41,36}. Below we model two processes that exchange a binary tree.

$$\text{Sender}(x) = \text{rec } \varpi. (\text{leaf } \varpi(x) \lor \text{branch } \varpi(x, y, z)(\text{Sender}(y) \parallel \text{Sender}(z)))$$

$$\text{Receiver}(x, y) = \text{corec } x. \text{case } x \{ x() . \varpi, x(y, z).u(\text{Receiver}(y, u) \parallel u().\text{Receiver}(z, y)) \}$$

The Sender performs a non-deterministic choice corresponding to the structure of the tree to be communicated: if the tree is empty (that is a leaf), it sends the unit indicating that no further data will be transmitted; if the tree is not empty (that is a branch), it sends a pair of channels along which the left and right subtrees are communicated in parallel. The Receiver behaves in a dual way. After receiving leaf, it signals the completion of the communication by sending the unit on $y$. After receiving branch, it first receives the left subtree followed by the right subtree. The sequencing between these two phases is enforced by the communication on the new channel $u$.

It is easy to see that Sender uses $x$ according to the formula $\varphi \equiv \mu X.1 \lor (X \otimes X)$ and that Receiver uses $x$ and $y$ according to $\psi \equiv \nu X.\bot \sqcup (X \otimes X)$ and $1$, respectively. In particular, the $\otimes$ connective in $\psi$ plays the same role of sequential composition in context-free session types \cite{41}.
