A Single-Loop Gradient Descent and Perturbed Ascent Algorithm for Nonconvex Functional Constrained Optimization

Songtao Lu

Abstract

Nonconvex constrained optimization problems can be used to model a number of machine learning problems, such as multi-class Neyman-Pearson classification and constrained Markov decision processes. However, such kinds of problems are challenging because both the objective and constraints are possibly nonconvex, so it is difficult to balance the reduction of the loss value and reduction of constraint violation. Although there are a few methods that solve this class of problems, all of them are double-loop or triple-loop algorithms, and they require oracles to solve some subproblems up to certain accuracy by tuning multiple hyperparameters at each iteration. In this paper, we propose a novel gradient descent and perturbed ascent (GDPA) algorithm to solve a class of smooth nonconvex inequality constrained problems. The GDPA is a primal-dual algorithm, which only exploits the first-order information of both the objective and constraint functions to update the primal and dual variables in an alternating way. The key feature of the proposed algorithm is that it is a single-loop algorithm, where only two step-sizes need to be tuned. We show that under a mild regularity condition GDPA is able to find Karush-Kuhn-Tucker (KKT) points of nonconvex functional constrained problems with convergence rate guarantees. To the best of our knowledge, it is the first single-loop algorithm that can solve the general nonconvex smooth problems with nonconvex inequality constraints. Numerical results also showcase the superiority of GDPA compared with the best-known algorithms (in terms of both stationarity measure and feasibility of the obtained solutions).

1. Introduction

In this work, we consider the following class of nonconvex optimization problems under smooth nonconvex constraints

\[
\mathbb{P}1 \quad \min_{x \in \mathcal{X} \subseteq \mathbb{R}^d} \ f(x) \ \text{subject to} \ g(x) \leq 0 \quad (1)
\]

where functions \( f(x) : \mathbb{R}^d \to \mathbb{R} \) and \( g(x) : \mathbb{R}^d \to \mathbb{R}^m \) are smooth (possibly) nonconvex, \( \mathcal{X} \) denotes the feasible set, and \( m \) is the total number of constraints. This class of constrained optimization problems has been found very useful in formulating practical learning tasks, as the requirements of enhancing the interpretability of neural nets or safety and fairness guarantees raise. When the machine learning models are applied in different domains, functional constraint \( g(x) \) can be specialized to particular forms. For example, if the first-order logic is considered in modeling the reasoning behaviors among the inputs, logical constraints will be incorporated in the optimization process (Bach et al., 2017; Fischer et al., 2019). Also, in a safe reinforcement learning problem, safety-aware constraints, e.g., cumulative long-term rewards (Yu et al., 2019; Ding et al., 2020) or expected probability of failures (Bharadhwaj et al., 2021), will be included in the policy improvement step. Besides, in the design of deep neural nets (DNN) architectures, the energy consumption budget will be formulated as constraints in the DNN compression models (Yang et al., 2019). Different from the projection-friendly constraints, these constraints are (possibly) functional ones.

1.1. Motivating Examples

To be more specific, we give the following problems that can be formulated by (1) as the motivating examples of this work.

Multi-class Neyman-Pearson Classification (mNPC).

mNPC is a classic multi-class pattern recognition problem. The previous works (Weston and Watkins, 1998; Crammer and Singer, 2002) propose to formulate this problem as a constrained optimization problem and adopt the support vector machine method to find \( m \) classifiers. To be specific, it considers that there are \( m \) classes of data, where each of them contains a data set, denoted by \( \xi_i, i \in [m] \). The goal of the problem is to learn \( m \) classifiers, denoted by \( \{x(i)\} \),

so that the loss of a prioritized class is minimized while the rest ones are below a certain threshold denoted by $r_i$, i.e.,

$$\min_{\{x(i)\}} f_{\xi_i}(\{x(i)\}), \quad (2a)$$

subject to $f_{\xi_i}(\{x(i)\}) \leq r_i, i = 2, \ldots, m$, \quad (2b)

where $f_{\xi_i}$ denotes the (possible nonconvex) non-increasing loss function of each class, and here class 1 is set as the prioritized one.

Constrained Markov decision processes (CMDP). A CMDP is described by a tuple $(\mathcal{S}, \mathcal{A}, P, R, G, \gamma)$, where $\mathcal{S}$ is the state space, $\mathcal{A}$ is the action space of an agent, $P$ denotes the state transition probability of the MDP, $R$ is the reward, $G_i, i \in [m]$ are budget-related rewards, and $\gamma$ denotes the discounted factor (Sutton and Barto, 2018). A policy $\pi: \mathcal{S} \rightarrow \Delta \mathcal{A}$ of the agent is a function, mapping from the state space to action space, which determines a probability simplex $\Delta \mathcal{A}$. The goal of the policy improvement problem is to learn an optimal policy so that the cumulative rewards can be maximized at the agent under some expected utility constraints, which can be formulated as the following constrained problem with respect to $\pi$ (Ding et al., 2020):

$$\max_{\pi \in \Delta \mathcal{A}} \langle Q^\pi, \pi \rangle, \quad \text{subject to } \langle Q^\pi, \pi \rangle \geq b_i, \forall i \quad (3)$$

where $Q^\pi \triangleq (1 - \gamma)E[\sum_{t=0}^{\infty} \gamma^t R(S_t, A_t)|S_0 = s, A_0 = a]$ denotes the action value functions associated with policy $\pi$, and similarly $Q^\pi_i \triangleq (1 - \gamma)E[\sum_{t=0}^{\infty} \gamma^t G_i(S_t, A_t)|S_0 = s, A_0 = a], \forall i$ are the action value functions related to the constraints, $b_i, \forall i$ stand for the thresholds of each budget. In practice, policy $\pi$ is parametrized by a neural network. Again, the above CMDP problem is a nonconvex optimization problem with nonconvex functional constraints (1).

Deep neural networks training (DNN) under Energy Budget. One efficient technique to reduce the complexity of DNNs is model compression. Consider a layer-wise weights sparsification problem (Yang et al., 2019). Let $\mathbf{W}$ denote the stacks of weight tensors of all the layers, i.e., $\mathbf{W} \triangleq \{ \mathbf{w}(u) \}$, where $u$ is the index of layers, and $\mathbf{S} \triangleq \{ s(u) \}$ denote the stacks of the non-sparse weights of all the layers. Then, the energy-constrained DNN training problem can be written as

$$\min_{\mathbf{W}, \mathbf{S}} \ell(\mathbf{W}), \quad (4a)$$

subject to $\phi(\mathbf{w}(u)) \leq s(u), \psi(\mathbf{S}) \leq E_{\text{budget}}, \forall u \quad (4b)$

where $\ell(\mathbf{W})$ denotes the training loss, $s(u)$ corresponds to the sparsity level of layer $u$, $\phi(\mathbf{w}(u))$ calculates the layer-wise sparsity, $\psi(\mathbf{S})$ represents the energy consumption of the DNN, and constant $E_{\text{budget}}$ is the threshold of the maximum energy budget. Here, both $\phi$ and $\psi$ are potentially nonconvex functions with respect to $\mathbf{w}(u)$ and $\mathbf{S}$.

1.2. Related Work

Solving the nonconvex problems is a long-standing question in machine learning as well as other fields. When the constraints are linear equality constraints or convex constraints, many existing works study different types of algorithms to solve nonconvex objective function optimization problems, such as primal-dual algorithms (Hong et al., 2016; Hajinezhad and Hong, 2019; Zhang and Luo, 2020b; Zeng et al., 2022), inexact proximal accelerated augmented Lagrangian methods (Xu, 2019; Kong et al., 2019; Melo et al., 2020), trust-region approaches (Cartis et al., 2011), to just name a few.

Penalty based Methods. When the objective function and constraints are both nonconvex, there is a penalty based method, called penalty dual decomposition method (PDD) (Shi and Hong, 2020), which 1) directly penalizes the nonconvex constraint function to the objective; 2) solves the problem based on the new surrogate function; 3) then check the feasibility of the obtained solution; 4) if the constraint is not satisfied then increase the penalty parameter and go back to 2). Although it is shown that PDD can solve a wide range of nonconvex constrained problems, the convergence complexity is not obtained. Based on the proximal point method and the quadratic penalty method, an inexact proximal-point penalty (IPPP) method (Lin et al., 2022) is the first penalty-based method that can converge to the Karush-Kuhn-Tucker (KKT) points for nonconvex objective and constraints problems.

Inexact Augmented Lagrangian Method. The inexact augmented lagrangian method (IALM) is one of the most popular ones that solve the nonconvex optimization problems with constraints. The main idea of this family of algorithms is to add a quadratic term (proximal term) to the augmented Lagrangian function so that the resulting surrogate of the loss function becomes strongly convex and can be solved efficiently by leveraging the existing computationally efficient accelerated first-order methods as an oracle or subroutine. For an equality nonlinear/nonconvex constrained problem, IALM is proposed in (Sahin et al., 2019; Xie and Wright, 2021) with quantifiable convergence rate guarantees to find KKT points of nonlinear constrained problems. For inequality non-convex constrained problems, inexact quadratically regularized constrained (IQR) methods (Ma et al., 2020; Boob et al., 2022) are proposed recently for solving problem (1), which are developed based on the Moreau envelope notation of stationary points/KKT points under a uniform Slater regularity condition. Although these works are able to solve the nonconvex constrained problems, all of them require double or triple inner loops, which makes the implementation of these algorithms complicated and time-consuming. A short summary of the existing algorithms for solving nonconvex problems is shown in Table 1.

2. Gradient Descent and Perturbed Ascent Algorithm

First, we can write down the Lagrangian function of problem (1) as \( \mathcal{L}(x, \lambda) = f(x) + \langle g(x), \lambda \rangle \) (5)

where non-negative \( \lambda \in \mathbb{R}_+^m \) denotes the dual variable (Lagrangian multiplier).

Instead of designing an algorithm based on optimizing the original Lagrangian function, we propose to construct the following perturbed augmented Lagrangian function:

\[
F_\beta(x, \lambda) \triangleq f(x) + \frac{\beta}{2} \left\| g(x) + \frac{(1 - \tau)\lambda}{\beta} \right\|^2 - \frac{\| (1 - \tau)\lambda \|^2}{2\beta} \quad (6)
\]

where \( [x]_+ \) denotes the component-wise nonnegative part of vector \( x \), \( \beta > 0 \), and constant \( \tau \in (0, 1) \). Here, perturbation term \( \tau \) plays the critical role of ensuring the convergence of the designed algorithm. (Please see Section 3.3 for more discussion.)

Next, we consider finding a stationary (quasi-Nash equilibrium) point (Pang and Scutari, 2011) of the following problem to solve the nonconvex constrained problem (1)

\[
\min_{x \in \mathcal{X}} \max_{\lambda \geq 0} F_\beta(x, \lambda). \quad (7)
\]

To this end, a single-loop GDPA algorithm is proposed as...
where $J$ berghe, 2004). As

$$\lambda_{r+1} = \arg \max_{\lambda \geq 0} \left( \frac{1}{1-\tau} - \frac{1-\tau}{2\beta_r} \|\lambda - \lambda_r\|^2 - \frac{\gamma_r}{2} \|\lambda\|^2 \right)$$  

(8b)

where

$$\beta_r \gamma_r \triangleq \tau \in (0, 1),$$

(9)

and we design that $\beta_r$ is an increasing sequence and subsequently $\gamma_r$ is a decreasing one.

Substituting (6) into (8a) yields

$$x_{r+1} = \arg \min_{x \in X} \left( \nabla f(x_r) + \beta_r J^T(x_r) \left[ g(x_r) \frac{1-\tau}{\beta_r} \right] + \frac{1}{2\alpha_r} \|x - x_r\|^2, \right.$$  

(10)

$$x_r - x_r + 1 \frac{1}{2\alpha_r} \|x - x_r\|^2,$$

(11)

where $J(x)$ denotes the Jacobian matrix of function $g(\cdot)$ at point $x$, $r$ is the index of iterations, $\alpha_r$ is the step-size of the minimization step.

Regarding the update of the dual variable, it is dependent on the functional constraints satisfaction. Let

$$\mathcal{S}_r \triangleq \left\{ i | g_i(x_r) + \frac{1-\tau}{\beta_r} [\lambda_r]_i > 0 \right\} ,$$

(12a)

where $g_i(x)$ denotes the $i$th constraint, and notation $\|x\|_i$ denotes the $i$th entry of vector $x$. Then, it is obvious that $g_i(x_r) \leq 0, i \in \mathcal{S}_r$. Substituting (6) into (8b) results in the following two cases of updating dual variable $\lambda$, which are

$$[\lambda_{r+1}]_i = \arg \max_{\lambda \geq 0} \left[ g_i(x_{r+1}) - [\lambda_r]_i - \frac{\gamma_r}{2} \|\lambda_i\|^2 \right.$$  

(12b)

$$- \frac{1-\tau}{\beta_r} \|\lambda_i - [\lambda_r]_i\|^2, \forall i \in \mathcal{S}_r$$

It can be seen that the update of primal variable $x$ in the minimization step is a standard one, which is optimizing the linearized function $F_{x_r}$ at point $(x_r, \lambda_r)$ with a proximal term. The perturbed dual update is the key innovation, where the perturbation parameter $\gamma_r$ adds the negative curvature to the maximization problem so that the dual update is well-behaved and easy to analyze. As $\gamma_r$ shrinks, the maximization step reduces to the classic update of the Lagrangian multiplier (Bertsekas, 1999; Boyd and Vandenberghe, 2004).

Note that GDPA is a single-loop algorithm and its updating rules (8), (10), (12) can be written equivalently in the following form, i.e.,

$$x_{r+1} = \mathcal{P}_X \left( x_r - \alpha_r \left( \nabla f(x_r) + J^T(x_r) \left[ (1-\tau)\lambda_r + \beta_r g(x_r) \right]_+ \right) \right),$$

(13a)

$$[\lambda_{r+1}]_i = \left\{ \mathcal{P}_{r+1} \left[ (1-\tau)\lambda_r + \beta_r g_i(x_{r+1}) \right], i \in \mathcal{S}_r, \right.$$  

(13b)

where $\mathcal{P}_X$ denotes the projection of iterates to the feasible set, $\mathcal{P}_{r+1} \triangleq [+]$ is the component-wise nonnegative projection operator, and $\beta_r$ serves as the step-size of the maximization step.

Remark 1. If subproblem in (10) is an unconstrained one, such as a machine learning model parametrized by a neural network, then $X = \mathbb{R}^d$, where $x$ denotes the weights. In this case, the update (13a) in GDPA reduces to $x_{r+1} = x_r - \alpha_r \left( \nabla f(x_r) + J^T(x_r) \left[ (1-\tau)\lambda_r + \beta_r g(x_r) \right]_+ \right)$.

3. Theoretical Guarantees

Before showing the theoretical convergence rate result of GDPA, we first make the following blanket assumption for problem (1).

3.1. Assumptions

Assumption 1. (Lipschitz continuity of function $f(x)$) We assume that $f(x)$ is smooth and has gradient Lipschitz continuity with constant $L_f$, i.e., $\|\nabla f(x) - \nabla f(y)\| \leq L_f \|x - y\|, \forall x, y \in X \subseteq \mathbb{R}^d$.

Assumption 2. (Lipschitz continuity of function $g(x)$) function $g(x)$ has function Lipschitz continuity with constant $L_g$, i.e., $\|g(x) - g(y)\| \leq L_g \|x - y\|, \forall x, y \in X \subseteq \mathbb{R}^d$, and the Jacobian function of $g(x)$ is Lipschitz continuous with constant $L_J$, i.e., $\|J(x) - J(y)\| \leq L_J \|x - y\|, \forall x, y \in X \subseteq \mathbb{R}^d$.

Assumption 3. (Boundedness of function $f(x)$) Further, we assume that the lower bound of $f(x)$ is $f^*$, i.e., $\min_{x \in X} f(x) > f^* > -\infty$, and the upper bound of the size of the gradient of $f(x)$ with respect to variable $x$ is $M$, i.e., $\|\nabla_x f(x)\| \leq M, \forall x \in X \subseteq \mathbb{R}^d$.

Assumption 4. (Boundedness of function $g(x)$) Assume that the size of function $g_+(x)$ is upper bounded by $G$, i.e., $\|g_+(x)\| \leq G, \forall x \in X \subseteq \mathbb{R}^d$, and the Jacobian function of $g(x)$ is upper bounded by $U_J$, i.e., $\|J(x)\| \leq U_J, \forall x \in X \subseteq \mathbb{R}^d$.

All the above assumptions are based on the functions themselves and standard in analyzing the convergence of algorithms. Alternatively, we can assume compactness of feasible set $X$ as follows.
**Assumption 5.** Assume that $\mathcal{X}$ is convex and compact.

Previous works (Sahin et al., 2019; Li et al., 2021; Ma et al., 2020; Lin et al., 2022) also assume the compactness of feasible sets, which imply Assumption 1 to Assumption 4 directly for smooth functions.

Due to the nonconvexity of the constraints, we need the following regularity condition to ensuring the feasibility of solutions with the functional nonconvex constraints.

**Assumption 6.** (Regularity condition) We assume that there exists a constant $\sigma > 0$ such that

$$\sigma \| g_+(x) \| \leq \text{dist} (J^T(x) g_+(x), -N_{\mathcal{X}}(x)) \quad (14)$$

where $\text{dist}(x, \mathcal{X}) \equiv \min_{y \in \mathcal{X}} \| x - y \|$ and $N_{\mathcal{X}}(x)$ denotes the normal cone of feasible set $\mathcal{X}$ at point $x$.

**Remark 2.** When $\mathcal{X} = \mathbb{R}^d$, condition (14) reduces to $\sigma \| g_+(x) \| \leq \| J^T(x) g_+(x) \|$.

The regularity qualification is required in solving constrained optimization problems, e.g., Slater’s condition, linear independence constraint qualification (LICQ), and so on, which is different from the unconstrained problems or the constrained one with closed-form projection operators. Condition (14) is a standard one and has been adopted to analyzing the convergence of iterative algorithms with nonconvex functional constrained problems (Sahin et al., 2019; Li et al., 2021; Lin et al., 2022).

### 3.2. Theoretical Guarantees

**Convergence Rate.** Next, we use the following measure to quantify the optimality of the iterates generated by GDPA:

$$\mathcal{G}(x, \lambda) \triangleq \left[ \frac{1}{\sqrt{\beta}} \| x - \text{proj}_{\mathcal{X}} \left( x - \alpha \nabla \mathcal{L}(x, \lambda) \right) \| \right]^\top \left[ \frac{1}{\sqrt{\alpha}} \| \lambda - \text{proj}_{\triangledown \mathcal{L}(x, \lambda)} \| \right], \quad (15)$$

where $\alpha, \beta > 0$. This optimality gap has been widely used in the theoretical analysis of nonconvex algorithms for solving constrained optimization problems (Hong et al., 2016) and nonconvex minmax problems (Lu et al., 2020). Besides, we need feasibility and slackness conditions in quantifying constraint satisfaction. Together with (15), approximate stationarity conditions are given as follows.

**Definition 1.** (\(\varepsilon\)-approximate Stationary Points) A point $x$ is called an \(\varepsilon\)-approximate stationary point of problem (1) if there is a $\lambda \geq 0$ such that

$$\| \mathcal{G}(x, \lambda) \| \leq \varepsilon. \quad (16)$$

Then, we provide the main theorem of the convergence rate of GDPA as follows.

**Theorem 1.** Suppose that Assumption 1-Assumption 4 (or Assumption 5) and Assumption 6 hold and iterates $\{x_r, \lambda_r, \forall r \geq 0\}$ are generated by GDPA. When the stepsizes are chosen as

$$\alpha_r \sim \gamma_r \sim \frac{1}{\beta_r} \sim \mathcal{O} \left( \frac{1}{r^\gamma} \right), \quad \gamma_r \beta_r = \tau, \quad (17)$$

and $\tau > 1 - \sigma/\sqrt{66U_2^2 + \sigma^2}$, there exist constants $K_1, K_2, K_3$ such that

$$\| \mathcal{G}(x_{T(\varepsilon)}), \lambda_{T(\varepsilon)} \| \leq \frac{K_1}{T(\varepsilon)^\frac{1}{2}}, \quad (18a)$$

$$\| g_+(x_{T(\varepsilon)}) \| \leq \frac{K_2}{T(\varepsilon)^\frac{1}{2}}, \quad (18b)$$

$$\sum_{i=1}^{m} \| x_{T(\varepsilon)} - \lambda_i g_i(x_{T(\varepsilon)}) \| \leq \frac{K_3}{T(\varepsilon)^\frac{1}{2}} \quad (18c)$$

where

$$T(\varepsilon) \triangleq \min \{ r \| g_+(x_{r+1}) \| \leq \varepsilon, r \geq 1 \}, \quad (19)$$

and outputs $x_{T(\varepsilon)} \triangleq (\sum_{i=1}^{T(\varepsilon)} 1/\beta_r)^{-1} x_r/\beta_r$, $\lambda_{T(\varepsilon)} \triangleq (\sum_{i=1}^{T(\varepsilon)} 1/\beta_r)^{-1} \lambda_r/\beta_r$.

Due to the space limit, all the detailed proofs in this paper are relegated to the supplemental material.

**Remark 3.** When $\mathcal{X} = \mathbb{R}^d$, then according to (5) and (15) it is concluded immediately that $\| \mathcal{G}(x, \lambda) \| \leq \varepsilon$ implies $\| \nabla f(x) + \sum_i \lambda_i \nabla g_i(x) \| \leq \varepsilon$.

**KKT Points** Based on the notation of quasi-Nash equilibrium points, we have obtained the convergence rate of GDPA to \(\varepsilon\)-approximate KKT point of problem (1) if there is a $\lambda \geq 0$ such that

$$\text{dist} \left( \nabla f(x) + \sum_{i=1}^{m} \lambda_i \nabla g_i(x), -N_{\mathcal{X}}(x) \right) \leq \varepsilon, \quad (20a)$$

$$\| g_+(x) \| \leq \varepsilon, \quad (20b)$$

$$\sum_{i=1}^{m} \| \lambda_i g_i(x) \| \leq \varepsilon. \quad (20c)$$

When $\varepsilon = 0$, then $\| \mathcal{G}(x, \lambda) \| = 0$ or more precisely $\| 1/\alpha [ x - \text{proj}_{\mathcal{X}} ( x - \alpha \nabla \mathcal{L}(x, \lambda)) ] \| = 0$ implies $\text{dist} \left( \nabla f(x) + \sum_{i=1}^{m} \lambda_i \nabla g_i(x), -N_{\mathcal{X}}(x) \right) = 0$. In this work, we also provide the following proposition to show the relation between the approximate stationary points (16) and (20a).
**Proposition 1.** When \( \mathcal{X} \) is convex, the stationarity of the approximate saddle points defined by (16) is a sufficient condition for (20a), namely if a point \( (\mathbf{x}, \lambda) \) satisfies \( \|1/\alpha [\mathbf{x} - \text{proj}_\mathcal{X}(\mathbf{x} - \alpha \nabla_x L(\mathbf{x}, \lambda))] \| \leq \epsilon, \alpha > 0 \), then it also satisfies (20a).

To show the above result, classic Farkas Lemma, (i.e., Lemma 12.4 in (Nocedal and Wright, 2006)) is not applicable since the definition of the separating hyperplane is built on the exact stationary points, i.e., the case where \( \epsilon = 0 \). However, here we need a notation of approximate stationary points of being able to quantify the convergence rate. Therefore, we give the following variant of approximate Farkas lemma, which bridges the connection between (16) and (20a).

**Lemma 1. (Approximate Farkas Lemma).** Let the cone \( K \) be defined as \( K = \{ By + Cw | y \geq 0 \} \) where \( B \in \mathbb{R}^{d \times m} \), \( C \in \mathbb{R}^{d \times p}, y \in \mathbb{R}^m, w \in \mathbb{R}^p \). Given any vector \( g \in \mathbb{R}^d \) and \( 0 < \epsilon < 1 \), we have either \((g + \Delta) \in K \) where \( \Delta \in K \) and \( \|\Delta\| \leq \epsilon \) or that there exists a \( d \in \mathbb{R}^d \) where \( \|d\| = 1 \) satisfying

\[
\begin{align*}
g^T d &< -\epsilon, \quad (21a) \\
B^T d &\geq 0, \quad (21b) \\
C^T d &= 0, \quad (21c)
\end{align*}
\]

but not both.

**Remark 4.** The main difference between Lemma 1 and the classic one is that the size of separating hyperplane \( d \) is bounded, otherwise, the error tolerance defined based on the inner product, i.e., \( (21a) \), is meaningless.

Combining Proposition 1, Theorem 1 claims that the proposed GDPA can find an approximate KKT point at a rate of \( O(1/\epsilon^3) \).

**Corollary 1.** Suppose that Assumption 1-Assumption 4 (or Assumption 5) and Assumption 6 hold and iterates \( \{\mathbf{x}_r, \lambda_r, \forall r \geq 0\} \) are generated by GDPA. When the step-sizes are chosen as \( \alpha_r \sim 1/\beta_r \sim O(1/r^{1/3}) \) and \( \gamma_r \beta_r = \tau > 1 - \sigma/\sqrt{64U^2 + \sigma^2} \), then the outputs of GDPA \( \mathbf{x}_{T(\epsilon)}, \lambda_{T(\epsilon)} \) converge to an \( \epsilon \)-approximate KKT point satisfying

\[
\text{dist} \left( \nabla f(\mathbf{x}_{T(\epsilon)}) + \sum_{i=1}^m \lambda_{T(\epsilon)} i \nabla g_i(\mathbf{x}_{T(\epsilon)}), -\mathcal{N}_\mathcal{X}(\mathbf{x}) \right) \leq \epsilon, \\
\|g_i(\mathbf{x}_{T(\epsilon)})\| \leq \epsilon, \quad \sum_{i=1}^m \|\lambda_{T(\epsilon)} i \| g_i(\mathbf{x}_{T(\epsilon)}) \| \leq \epsilon, \quad (22)
\]

in the number of \( O(1/\epsilon^3) \) iterations.

### 3.3. Convergence Analysis

The following theoretical results showcase the main ideas of measuring the convergence rate of GDPA to KKT points, where the key step is to derive the upper bound of the size of dual variable \( \lambda \).

**Perturbation.** The first result is that we found that after adding the perturbation the optimality gap defined in (15) will be upper bounded the successive difference between primal and dual variables plus a perturbed term \( \gamma_\tau^2 \|\lambda_{r+1}\|^2 \).

**Lemma 2.** Suppose that Assumption 1-Assumption 3 hold. If the iterates \( \{\mathbf{x}_r, \lambda_r, \forall r \} \) are generated by GDPA, where the step-sizes are chosen according to (17), then we have

\[
\begin{align*}
\|g_i(\mathbf{x}_r, \lambda_r)\|^2 &\leq 4 \left( \left( \frac{3}{\alpha_r} + L_g \right)^2 + 2U^2 g_i^2 \beta_r^2 \right) \|\mathbf{x}_{r+1} - \mathbf{x}_r\|^2 \\
&\quad + 4 \left( \frac{3 + \tau}{\beta_r^2} + 3 \right) \|\lambda_{r+1} - \lambda_r\|^2 + 4 \gamma_\tau^2 \|\lambda_{r+1}\|^2. \quad (23)
\end{align*}
\]

Under Assumption 1 to Assumption 3, we can know an upper bound of the first term on the right-hand side (RHS) of (23) by applying gradient Lipchitz continuity of \( F_g(\mathbf{x}, \lambda) \), and an upper bound of the second term on RHS of (23) by quantifying the strong concavity of \( F_g(\mathbf{x}, \lambda) \). Also, these upper bounds can be written as the difference between \( F_{\beta_r}(\mathbf{x}_{r+1}, \lambda_{r+1}) \) and \( F_{\beta_r}(\mathbf{x}_r, \lambda_r) \) in general. The major challenge is to get an upper bound of the last term in RHS of (23). From (13b), it is not hard to show that the upper bound of \( \lambda \) is \( O(\beta_r^2) \) under Assumption 4. However, it is implied from (9) that the last term on RHS of (23) is only upper bounded by a constant, giving rise to a constant error in the optimality gap.

**Boundness of Dual Variable.** The main idea of having a sharper upper bound of dual variable \( \lambda \) or sum of the last term on RHS of (23) is using the regularity condition (14), which provides certain contraction property on the size of \( \lambda \) up to some terms. The detailed claim is given as follows.

**Lemma 3.** Suppose that Assumption 1-Assumption 4 (or Assumption 5) and Assumption 6 hold. Let the active set at the \( r \)th iteration be

\[
A_r \triangleq \{i | g_i(\mathbf{x}_r) > 0\}. \quad (24)
\]

If the iterates \( \{\mathbf{x}_r, \lambda_r, \forall r\} \) are generated by GDPA, where the step-sizes are chosen according to (17), then we have

\[
\begin{align*}
\sigma^2 \|\lambda_{r+1}\|^2 &\leq 16M^2 + \frac{36}{\alpha_r^2} \|\mathbf{x}_{r+1} - \mathbf{x}_r\|^2 \\
&\quad + 64U^2 \|\lambda_{r+1} - \lambda_r\|^2 + 64(1 - \tau)^2 U^2 \|\lambda_r\|^2 \quad (25)
\end{align*}
\]

where \( \lambda_{r+1} \) is a vector whose \( i \)th entry is

\[
[\lambda_{r+1}]_i = \begin{cases} 
[\lambda_{r+1}]_i, & \text{if } i \in A_{r+1} \cap S_r; \\
0, & \text{otherwise}. 
\end{cases} \quad (26)
\]
Due to the nonnegativity of $\lambda_r$ and $\tau \in (0, 1)$, we know that when $g_i(x_r + 1) \leq 0$, we have the following contraction property from (13b)
\[
[\lambda_{r+1}]_i \leq (1 - \tau)[\lambda_r]_i, \quad \forall i \in \mathcal{A}_{r+1} \cap S_r.
\]
Combing (25) and (27), we can have a contraction property of the size of the dual variable with some additional terms when $\tau$ is close to 1, which demonstrates the importance and reason of adding the perturbation term in the dual update. Based on the fact, we are able to have the following encouraging result.

**Lemma 4.** Suppose that Assumption 1-Assumption 4 (or Assumption 5 ) and Assumption 6 hold. If the iterates $\{x_r, \lambda_r, \forall r\}$ are generated by GDPA, where the step-sizes are chosen according to (17), then we have
\[
\sum_{r=1}^{T} \alpha_r^2 \|\lambda_r\|^2 \sim O(T^{1/3}),
\]
where $T$ denotes the total number of iterations.

Note that $\alpha_r \sim \gamma_r$, from (17) we have $\sum_{r=1}^{T} \alpha_r^2 \|\lambda_r\|^2 \sim O(T^{1/3})$. If we only use Assumption 4 to get the upper bound of $\gamma_r^2 \|\lambda_r\|^2$, we will have $\sum_{r=1}^{T} \alpha_r^2 \|\lambda_r\|^2 \sim O(T)$, resulting in failure to show the convergence GDPA to KKT points.

4. Discussion

4.1. Regularity Condition

The regularity condition (14) has been proven to hold for many practical problems, such as a certain kind of mNPC problems (Lin et al., 2022), clustering and basis pursuit problems (Sahin et al., 2019) under some mild conditions on initializations. Also, the variant of this condition for functional linear equality constraints holds automatically for either feasible set $X$ is a ball constraint or a compact polyhedral one (Li et al., 2021).

4.2. Comparison with Existing Works

**Penalty based Method.** Comparing with the penalty-based methods (Shi and Hong, 2020; Lin et al., 2022), primal-dual methods can deal with the multiple nonconvex constraints more flexibly, since the dual variable takes the variety of constraints automatically. Numerically, the primal-dual type of algorithms converges, in general, faster than the penalty based method. But theoretical analysis of the penalty-based method is easier and more accessible due to the simplicity of the algorithms. Besides, the regularity condition (14) used in this work is the same as (Lin et al., 2022), and the convergence rate achieved by IPPP is $O(1/\epsilon^3)$.

**Primal Based Methods.** IQRC (Ma et al., 2020) is designed based on a uniform regularity condition, which is different from (14) and not easily verified. The inner loop of IQRC is realized by an accelerated gradient descent method, where the overall iteration complexity is $O(1/\epsilon^{3})$ for solving problem (1). The convergence analysis is neat due to the design of the algorithm, which focuses on optimizing the constraints first and then switching to optimize the objective function after the constraints are satisfied.

**Inexact Augmented Lagrangian Method.** IALM type of algorithms, e.g., (Sahin et al., 2019; Li et al., 2021) is the most popular one in solving problems with equality nonconvex constraints, where the convergence rate of IALM to find the KKT points of problem (1) is $O(1/\epsilon^4)$ (Sahin et al., 2019) or $O(1/\epsilon^3)$ (Li et al., 2021) under an almost identical regularity condition as (14). The main issue of this class of algorithms is that they use a rather small step-size for the dual variable update, and the performance of IALM varies significantly based on the different problems due to the nested structure in terms of loops.

Overall, all these algorithms are double-loop or triple-loop ones, and they all use the accelerated methods to solve the inner loop problems so that a fast theoretical convergence rate is obtained. As there are more than one inner loops in these algorithms, their implementations will involve tunings of multiple hyperparameters, while GDPA only needs to adjust the two step-sizes and one hyperparameter (which is quite insensitive to the convergence behavior of GDPA numerically). Our theoretical analysis of GDPA is also unique, which is established on a new way of showing the boundedness of dual variables.

5. Numerical Experiments

**mNPC problem.** We compare the convergence performance of the proposed GDPA algorithm with other existing ones, including IALM (Sahin et al., 2019; Li et al., 2021), IQRC (Ma et al., 2020), and IPPP (Lin et al., 2022), on a mNPC problem. We divide the MNIST dataset (LeCun et al., 1998) into $m + 1$ parts according to the classes of handwritten digits, and consider identifying digit 1 as the prioritized learning class while the other $m$ digits as the secondary ones and each digit as one task. The loss functions of constraints are $\sum_i \phi_j(x_{(i)}) \leq r_j$, where $\phi_j(x_{(i)})$ is just a sigmoid function $1/(1 + \exp(z))$ as used in (Lin et al., 2022; Ma et al., 2020), $z = (x_{(i)} - x_{(i)})^T \zeta_j, j \neq i$, and the objective loss function is $\frac{1}{2} \sum_i \|x_{(i)}\| + \sum_i \phi_1(x_{(i)})$ for $\lambda > 0$. Also, the input dimension is 784 (i.e., an image size of $28 \times 28$). Since the classification problem on the MNIST dataset is not a hard one in general, we add some random noise at each pixel on the images, where each entry of the noise follows the $i.i.d$ Gaussian distribution, so that the constraints are not easily satisfied. More detailed settings of this numerical experiment can be found in the Section F. It can be observed in Figure 1 that our proposed GDPA converges faster in orders of magnitude compared with the other
A Single-Loop Gradient Descent and Perturbed Ascent Algorithm for Nonconvex Functional Constrained Optimization

(b) Feasibility

(b) Feasibility

Figure 2. Computational time comparison of GDPA, IALM, IQRC, IPPP.

benchmarks in terms of computational time. All the IAML type of algorithms with being able to deal with nonconvex constraints is developed based on the functional equality nonconvex constraints, so we add a nonnegative slack variable to reformulate the inequality constrained problem (1) as an equality one. More detailed settings of this numerical experiment can be found in the Section F.

Neural Nets Training with Budget Constraints. We also test these algorithms on a training problem with some accuracy budget for fair learning problems, i.e.,

\[
\min_{\mathbf{W}} l_1(\mathbf{W}), \quad \text{subject to} \quad l_i(\mathbf{W}) \leq 1, \quad i = 2, \ldots, m + 1
\]

where we also use the MNIST dataset and again split the dataset as \(m + 1\) parts based on the class of digits, \(l_1(\mathbf{W})\) denotes the loss of training the neural net on digit 1, \(l_i(\mathbf{W})\) for digits 2, 3, 4, 5, 6 with \(m = 5\). The goal of this problem is to train the neural nets on a prioritized dataset with limited accuracy loss on the other ones.

The results are shown in Figure 2. It can be observed that the proposed GDPA converges faster than the rest of the methods in terms of computing time, showing the computational efficiency of single-loop algorithms compared with the double-loop or triple-loop ones. Also, we can see that IQRC shows a faster convergence rate in terms of constraint satisfaction since it first optimizes the constraints and then back to minimize the objective function values if the constraint violation has been achieved to a small predefined error. It is worth noting that in this case IALM performs worse than IPPP.

6. Concluding Remark

In this work, we proposed the first single-loop algorithm for solving general nonconvex optimization problems with functional non-convex constraints. Under a mild regularization condition, we show that the proposed GDPA is able to converge to KKT points of this class of non-convex problems at a rate of \(O(1/\epsilon^4)\). To the best of knowledge, this is the first theoretical result that a single-loop gradient primal-dual (i.e., gradient descent and ascent) algorithm can solve the nonconvex functional constrained problems with the same provable convergence rate guarantees as the double- and/or triple-loop algorithms.
References

A. Preliminaries

Before showing the detailed derivations of the lemmas and theorems, we first list the following notations and inequalities used in the proofs.

A.1. Notations

The following facts would help understand the relation between the satisfaction of the functional constraints and the perturbed augmented Lagrangian function.

1. Expression of $F_{\beta_r}(x, \lambda)$

From (6), we observe that when $g(x) + \frac{(1-\tau)\lambda}{\beta_r} > 0$, then

$$F_{\beta_r}(x, \lambda) = f(x) + \langle (1-\tau)\lambda, g(x) \rangle + \frac{\beta_r}{2} \|g(x)\|^2.$$  \hspace{1cm} (29)

When $\left[g(x) + \frac{(1-\tau)\lambda}{\beta_r}\right]_+ \leq 0$, then we have

$$F_{\beta_r}(x, \lambda) = f(x) - \frac{\|(1-\tau)\lambda\|^2}{2\beta_r}.$$  \hspace{1cm} (30)

Towards this end, recall

$$S_r \triangleq \left\{ i \mid g(x_r) + \frac{(1-\tau)\lambda_r}{\beta_r} > 0 \right\},$$

then we have

$$F_{\beta_r}(x, \lambda) = f(x) + \sum_{i \in S_r} (1-\tau)\lambda_i g_i(x) + \frac{\beta_r}{2} g_i^2(x) - \sum_{j \in S_r} \frac{(1-\tau)^2 \lambda_j^2}{2\beta_r}$$  \hspace{1cm} (31)

where $[x]_i$ denotes the $i$th entry of vector $x$, $S_r$ represents the complement of set $S_r$.

From (6), we know that the gradient of $F_{\beta_r}(x, \lambda)$ with respect to $x$ is

$$\nabla_x F_{\beta_r}(x, \lambda) \triangleq \nabla f(x) + J^T(x) [(1-\tau)\lambda + \beta_r g(x)]_+.$$  \hspace{1cm} (32)

2. Dual variable: based on the constraints satisfaction, we split the corresponding dual variables as two parts, i.e., $\lambda_i'$ and $\lambda_i^g$:

$$[\lambda_i']_i = \begin{cases} [\lambda_i]_i, & \text{if } i \in S_r; \\ 0, & \text{otherwise}. \end{cases}, \quad [\lambda_i^g]_i = \begin{cases} [\lambda_i]_i, & \text{if } i \in \overline{S}_r; \\ 0, & \text{otherwise}. \end{cases}$$  \hspace{1cm} (33)

and we have $|S_r| + |\overline{S}_r| = m_r$, $\|\lambda_i' + \lambda_i^g\|^2 + \|\lambda_i' - \lambda_i^g\|^2 = \|\lambda_i'\|^2$, $\|\lambda_i'\|^2 = \|\lambda_i\|_r^2$, $\|\lambda_i'\|^2 = \|\lambda_i\|^2$.

Dual variable $\lambda_i^{g+}$ and corresponding $\lambda_i^{g-}$ are defined based on the constraints satisfaction at $x_r$ and $x_{r+1}$:

$$[\lambda_i^{g+}]_i = \begin{cases} [\lambda_i']_i, & \text{if } i \in A_{r+1} \cap S_r; \\ 0, & \text{otherwise}. \end{cases}, \quad [\lambda_i^{g-}]_i = \begin{cases} [\lambda_i]_i, & \text{if } i \in A_{r+1} \cap \overline{S}_r; \\ 0, & \text{otherwise}. \end{cases}$$  \hspace{1cm} (34)

Dual variable $\overline{\lambda}_i^{g+}$ and corresponding $\overline{\lambda}_i^{g-}$ are defined based on the constraints satisfaction at $x_r$ and $x_{r+1}$:

$$[\overline{\lambda}_i^{g+}]_i = \begin{cases} [\lambda_i]_i, & \text{if } i \in A_{r+1} \cap S_r; \\ 0, & \text{otherwise}. \end{cases}, \quad [\overline{\lambda}_i^{g-}]_i = \begin{cases} [\lambda_i]_i, & \text{if } i \in A_{r+1} \cap \overline{S}_r; \\ 0, & \text{otherwise}. \end{cases}$$  \hspace{1cm} (35)
3. Functional constraints:

Similarly, we define functional constraints $g_1(x_{r+1})$ and $g'(x_{r+1})$ based on the constraints satisfaction as well, i.e.,

$$[g_1(x_{r+1})]_i = \begin{cases} g_i(x_{r+1}), & \text{if } i \in S_r; \\ 0, & \text{otherwise.} \end{cases}, \quad [g'(x_{r+1})]_i = \begin{cases} g_i(x_{r+1}), & \text{if } i \in A_{r+1} \cap S_r; \\ 0, & \text{otherwise.} \end{cases} \quad (36)$$

Also, functional constraints $\overline{g}(x_{r+1})$ and $\overline{g}'(x_r)$ are defined as follows:

$$[\overline{g}(x_{r+1})]_i = \begin{cases} g_i(x_{r+1}), & \text{if } i \in A_{r+1} \cap S_r; \\ 0, & \text{otherwise.} \end{cases}, \quad [\overline{g}'(x_r)]_i = \begin{cases} g_i(x_r), & \text{if } i \in A_{r+1} \cap S_r; \\ 0, & \text{otherwise.} \end{cases} \quad (37)$$

A.2. Inequalities

1. Quadrilateral identity:

$$\langle v_{r+1}, \lambda_{r+1} - \lambda_r \rangle = \frac{1}{2} \left( \|\lambda_{r+1} - \lambda_r\|^2 + \|v_{r+1}\|^2 - \|\lambda_r - \lambda_{r-1}\|^2 \right) \quad (38)$$

where

$$v_{r+1} \triangleq \lambda_{r+1} - \lambda_r - (\lambda_r - \lambda_{r-1}). \quad (39)$$

2. Young’s inequality with parameter $\theta > 0$:

$$\langle x, y \rangle \leq \frac{1}{2\theta} \|x\|^2 + \frac{\theta}{2} \|y\|^2, \quad \forall x, y. \quad (40)$$

A.3. Relation Among the Lemmas in the Proof

During the theorem proving process, we will first show the descent lemma and then quantify the maximum ascent after the dual update Lemma 5. Next, from the dual update, we find the recursion of successive difference between two iterates Lemma 6 so that we can construct a potential function that shows the possible progress after one round of updating primal and dual variables Lemma 7. Giving the upper bound of the dual variable is a preliminary step shown in Lemma 8 for functional constraints satisfaction. The key step is shown in Lemma 4 that sharpens the bound of measuring the size of a sum of dual variables by using the regularity condition Lemma 3, which plays the important role of characterizing the convergence of GDPA. At the same time, the optimality criterion is derived in terms of the successive difference of variables and the size of dual variables Lemma 2 so that we can use the obtained potential function to evaluate the descent achieved by GDPA. Combing these results together leads to the main theorem (Theorem 1) of quantifying the convergence rate of GDPA to KKT points.
B. On the Descent and Ascent of Potential Function

In this section, we will provide detailed proofs of the convergence rate of GDPA. First, we give the following descent lemma that quantifies the decrease of the objective value after performing one round of GDPA update.

**B.1. Descent Lemma**

**Lemma 5.** Suppose that Assumption 1–Assumption 3 hold. If the iterates \( \{x_r, \lambda_r, \forall r \} \) are generated by GDPA and the step-sizes \( \alpha_r \) and \( \beta_r \) satisfy

\[
\frac{1}{\alpha_r} \geq L_f + (1 - \tau)\parallel \lambda_r \parallel L_J + \beta_r U_J L_g,
\]

then, we have

\[
F_{\beta_{r+1}}(x_{r+1}, \lambda_{r+1}) - F_{\beta_r}(x_r, \lambda_r) \\
\leq \frac{1 - \tau}{2\beta_r} \parallel \lambda_r - \lambda_{r-1} \parallel^2 - \left( \frac{1}{2\alpha_r} - \frac{(1 - \tau)\beta_r L_g^2}{2}\right) \parallel x_{r+1} - x_r \parallel^2 \\
+ \frac{1 - \tau}{\beta_r} \parallel \lambda_{r+1} - \lambda_r \parallel^2 + (\beta_{r+1} - \beta_r)\parallel g_1(x_{r+1}) \parallel^2 + \left( \frac{1}{\beta_r} - \frac{1}{\beta_{r+1}} \right) (1 - \tau)^2 \parallel \lambda_{r+1} \parallel^2 \\
+ \frac{(1 - \tau)\gamma_{r-1}}{2} \parallel \lambda_r \parallel^2 + (1 - \tau) (\gamma_{r-1} - \gamma_r) \parallel \lambda_{r+1} \parallel^2. \tag{42}
\]

**Proof.** The proof mainly include two parts: 1) quantify the decrease of \( F_{\beta_r} \) when primal variable \( x \) is updated; 2) measure the ascent of \( F_{\beta_r} \) after dual variable \( \lambda \) is updated and \( \beta_r \) is changed to \( \beta_{r+1} \).

**Part 1 Update of** \( x \) \( \{ (x_r, \lambda_r) \rightarrow (x_{r+1}, \lambda_r) \} \).

According to the gradient Lipschitz continuity shown in Assumption 1–Assumption 3 and (32), we have

\[
F_{\beta_r}(x_{r+1}, \lambda_r) \leq F_{\beta_r}(x_r, \lambda_r) + \langle \nabla F_{\beta_r}(x_r, \lambda_r), x_{r+1} - x_r \rangle + \frac{L_f + (1 - \tau)\parallel \lambda_r \parallel L_J + \beta_r U_J L_g}{2} \parallel x_{r+1} - x_r \parallel^2 \tag{43}
\]

where we use the fact that the gradient Lipschitz constant is \( L_f \) when \( \left[ g_i(x_r) + \frac{(1 - \tau)\parallel \lambda_r \parallel}{\beta_r} \right] \geq 0, i \in S_r \) and \( L_f + (1 - \tau)\parallel \lambda_r \parallel L_J + \beta_r U_J L_g \) when \( \left[ g_i(x_r) + \frac{(1 - \tau)\parallel \lambda_r \parallel}{\beta_r} \right] \geq 0, i \in S_r \).

From the optimality condition of subproblem-\( x \), we have

\[
(x_{r+1} - x - \alpha_r \nabla F_{\beta_r}(x_r, \lambda_r)), x_r - x_{r+1} \geq 0. \tag{44}
\]

Therefore, substituting (44) into (43), we have

\[
F_{\beta_r}(x_{r+1}, \lambda_r) - F_{\beta_r}(x_r, \lambda_r) \leq - \left( \frac{1}{\alpha_r} - \frac{L_f + (1 - \tau)\parallel \lambda_r \parallel L_J + \beta_r U_J L_g}{2} \right) \parallel x_{r+1} - x_r \parallel^2. \tag{45}
\]

It can be seen that when

\[
\frac{1}{\alpha_r} \geq L_f + (1 - \tau)\parallel \lambda_r \parallel L_J + \beta_r U_J L_g,
\]

there is at least a decrease of \( F_{\beta_r} \) in terms of \( 1/(2\alpha_r)\parallel x_{r+1} - x_r \parallel^2 \) after the update of variable \( x \).

**Part 2 Update of** \( \lambda \) \( \{ (x_{r+1}, \lambda_r) \rightarrow (x_{r+1}, \lambda_{r+1}) \} \). There are two sub-cases in this part when \( \lambda \) is updated. To be more specific, we split partition \( \sum_{i \in S_r} (1 - \tau)\lambda_i g_i(x) - \sum_{j \in \mathcal{S}} \frac{(1 - \tau)^2\lambda_j^2}{2\beta_r} \) in function \( F_{\beta_r} \) (31) as the following two parts, i.e.,

\[
h_1(x, \lambda_r) \triangleq \sum_{i \in \mathcal{S}_r} \lambda_i g_i(x), \tag{47a}
\]

\[
h_2(x, \lambda_r) \triangleq - \sum_{i \in \mathcal{S}_r} \frac{(1 - \tau)\lambda_i^2}{2\beta_r}. \tag{47b}
\]
Then, from (31), we have
\[ F_{\beta_r}(x, \lambda_r) = f(x) + \sum_{i \in S_r} \frac{\beta_r}{2} g_i^2(x) + (1 - \tau) \left( h_1(x, \lambda_r) + h_2(x, \lambda_r) \right). \]  

(48)

2.1 Concave in dual: Let \( h'_i(x, \lambda_r) \triangleq \sum_{i \in S_r} \lambda_i g_i(x) - \mathbb{I}(\lambda'_r) \), where \( \mathbb{I}(\lambda'_r) \) denotes the indicator function. In this case, \( \lambda_i, \forall i \in S_r \) are linear in \( h_1(x, \lambda_r) \).

Then, since function \( h'_i(x, \lambda_r) \) is concave with respect to \( \lambda'_r \), we have
\[ h'_i(x_{r+1}, \lambda'_{r+1}) - h'_i(x_{r+1}, \lambda'_r) \leq \langle \nabla h_1(x_{r+1}, \lambda'_r), \lambda'_{r+1} - \lambda'_r \rangle - \langle \xi_r, \lambda'_{r+1} - \lambda'_r \rangle \]
\[ = \langle g_1(x_{r+1}), \lambda'_{r+1} - \lambda'_r \rangle - \langle \xi_r + \gamma_r - \tau \rangle - \langle \xi_r - \xi_r, \lambda'_{r+1} - \lambda'_r \rangle \]
\[ = \frac{1 - \tau}{\beta_r} \| \lambda'_{r+1} - \lambda'_r \|^2 + \gamma_r \langle \lambda'_{r+1}, \lambda'_{r+1} - \lambda'_r \rangle - \langle \xi_r + \gamma_r - \tau \rangle - \langle \xi_r - \lambda'_{r+1} + \lambda'_r \rangle \]
\[ = \frac{1 - \tau}{\beta_r} \| \lambda'_{r+1} - \lambda'_r \|^2 + \frac{\beta_r L^2}{2} \| x_{r+1} - x_r \|^2 + \frac{1}{2\beta_r} \| \lambda'_{r+1} - \lambda'_r \|^2 + \gamma_r \langle \lambda'_{r+1}, \lambda'_{r+1} - \lambda'_r \rangle - \langle \xi_r + \gamma_r - \tau \rangle - \langle \xi_r - \lambda'_{r+1} + \lambda'_r \rangle \]
\[ = \frac{1 - \tau}{\beta_r} \| \lambda'_{r+1} - \lambda'_r \|^2 + \frac{\beta_r L^2}{2} \| x_{r+1} - x_r \|^2 + \gamma_r \langle \lambda'_{r+1}, \lambda'_{r+1} - \lambda'_r \rangle - \langle \xi_r + \gamma_r - \tau \rangle - \langle \xi_r - \lambda'_{r+1} + \lambda'_r \rangle \]
\[ = \frac{1 - \tau}{\beta_r} \| \lambda'_{r+1} - \lambda'_r \|^2 + \frac{\beta_r L^2}{2} \| x_{r+1} - x_r \|^2 + \gamma_r \langle \lambda'_{r+1}, \lambda'_{r+1} - \lambda'_r \rangle - \langle \xi_r + \gamma_r - \tau \rangle - \langle \xi_r - \lambda'_{r+1} + \lambda'_r \rangle \]
\[ \leq \frac{\gamma_r - \gamma_r}{\beta_r} \| \lambda'_{r+1} - \lambda'_r \|^2 + \frac{\gamma_r - \gamma_r}{\beta_r} \| \lambda'_{r+1} - \lambda'_r \|^2 \]
\[ \leq \frac{\gamma_r - \gamma_r}{\beta_r} \| \lambda'_{r+1} - \lambda'_r \|^2 + \frac{\gamma_r - \gamma_r}{\beta_r} \| \lambda'_{r+1} - \lambda'_r \|^2 \]

where in (a) we use the optimality condition of \( \lambda \)-problem, i.e.,
\[ \xi_{r+1} - g_1(x_{r+1}) + \frac{1}{\beta_r} \langle \lambda'_{r+1} - \lambda'_r \rangle + \gamma_r \lambda'_{r+1} = 0, \]  

(51)

and in (b) we substitute
\[ \langle \xi_r + \gamma_r - \tau \rangle - \langle \xi_r - \lambda'_{r+1} + \lambda'_r \rangle \]
\[ = \frac{1 - \tau}{\beta_r} \| \lambda'_{r+1} - \lambda'_r \|^2 + \frac{\beta_r L^2}{2} \| x_{r+1} - x_r \|^2 + \gamma_r \langle \lambda'_{r+1}, \lambda'_{r+1} - \lambda'_r \rangle - \langle \xi_r + \gamma_r - \tau \rangle - \langle \xi_r - \lambda'_{r+1} + \lambda'_r \rangle \]  

(52)

and (c) is true because we use the following inequality
\[ \langle g_1(x_{r+1}) - g_1(x_r), \lambda'_{r+1} - \lambda'_r \rangle \leq \frac{\beta_r L^2}{2} \| x_{r+1} - x_r \|^2 + \frac{1}{2\beta_r} \| \lambda'_{r+1} - \lambda'_r \|^2 \]  

(53)

by applying the gradient Lipschitz continuity and Young’s inequality, and in (d) we apply quadrilateral identity (38) and the following fact
\[ \gamma_r - \tau \langle \lambda'_{r+1}, \lambda'_{r+1} - \lambda'_r \rangle \]
\[ = \frac{\gamma_r - \gamma_r}{\beta_r} \| \lambda'_{r+1} - \lambda'_r \|^2 + \frac{\gamma_r - \gamma_r}{\beta_r} \| \lambda'_{r+1} - \lambda'_r \|^2 \]
\[ = \frac{\gamma_r - \gamma_r}{\beta_r} \| \lambda'_{r+1} - \lambda'_r \|^2 + \frac{\gamma_r - \gamma_r}{\beta_r} \| \lambda'_{r+1} - \lambda'_r \|^2 \]
\[ = \frac{\gamma_r - \gamma_r}{\beta_r} \| \lambda'_{r+1} - \lambda'_r \|^2 + \frac{\gamma_r - \gamma_r}{\beta_r} \| \lambda'_{r+1} - \lambda'_r \|^2 \]
\[ = \frac{\gamma_r - \gamma_r}{\beta_r} \| \lambda'_{r+1} - \lambda'_r \|^2 + \frac{\gamma_r - \gamma_r}{\beta_r} \| \lambda'_{r+1} - \lambda'_r \|^2 \]
\[ = \frac{\gamma_r - \gamma_r}{\beta_r} \| \lambda'_{r+1} - \lambda'_r \|^2 + \frac{\gamma_r - \gamma_r}{\beta_r} \| \lambda'_{r+1} - \lambda'_r \|^2 \]
\[ = \frac{\gamma_r - \gamma_r}{\beta_r} \| \lambda'_{r+1} - \lambda'_r \|^2 + \frac{\gamma_r - \gamma_r}{\beta_r} \| \lambda'_{r+1} - \lambda'_r \|^2 \]
\[ = \frac{\gamma_r - \gamma_r}{\beta_r} \| \lambda'_{r+1} - \lambda'_r \|^2 + \frac{\gamma_r - \gamma_r}{\beta_r} \| \lambda'_{r+1} - \lambda'_r \|^2 \]
\[ = \frac{\gamma_r - \gamma_r}{\beta_r} \| \lambda'_{r+1} - \lambda'_r \|^2 + \frac{\gamma_r - \gamma_r}{\beta_r} \| \lambda'_{r+1} - \lambda'_r \|^2 \]
\[ = \frac{\gamma_r - \gamma_r}{\beta_r} \| \lambda'_{r+1} - \lambda'_r \|^2 + \frac{\gamma_r - \gamma_r}{\beta_r} \| \lambda'_{r+1} - \lambda'_r \|^2 \]
\[ = \frac{\gamma_r - \gamma_r}{\beta_r} \| \lambda'_{r+1} - \lambda'_r \|^2 + \frac{\gamma_r - \gamma_r}{\beta_r} \| \lambda'_{r+1} - \lambda'_r \|^2 \]
\[ = \frac{\gamma_r - \gamma_r}{\beta_r} \| \lambda'_{r+1} - \lambda'_r \|^2 + \frac{\gamma_r - \gamma_r}{\beta_r} \| \lambda'_{r+1} - \lambda'_r \|^2 \]
\[ = \frac{\gamma_r - \gamma_r}{\beta_r} \| \lambda'_{r+1} - \lambda'_r \|^2 + \frac{\gamma_r - \gamma_r}{\beta_r} \| \lambda'_{r+1} - \lambda'_r \|^2 \]
\[ = \frac{\gamma_r - \gamma_r}{\beta_r} \| \lambda'_{r+1} - \lambda'_r \|^2 + \frac{\gamma_r - \gamma_r}{\beta_r} \| \lambda'_{r+1} - \lambda'_r \|^2 \]

2.2 Strongly concave in dual: Let \( h'_2(\lambda) = -\sum_{i \in S_r} \frac{(1 - \tau)\| \lambda_i \|^2}{\beta_r} - \mathbb{I}(\lambda'_r) \), where \( \mathbb{I}(\lambda'_r) \) denotes the indicator function. In addition, let \( \xi' \) denote the subgradient of \( \mathbb{I}(\lambda'_r) \). In this case, \( \lambda_i, \forall i \in S_r \) are strongly concave in \( h_2(\lambda) \).
Then, we have
\[
\begin{align*}
& h'_2(x_{r+1}, \bar{x}_{r+1}) - h'_2(x_{r+1}, \bar{x}_r) \\
& \leq \langle \nabla h_2(x'_r), x_{r+1} - x'_r \rangle - \langle \xi'_r, x_{r+1} - x'_r \rangle \\
& = \langle \nabla h_2(x'_r), x_{r+1} - x'_r \rangle - \langle \xi'_r, x_{r+1} - x'_r \rangle - \langle \xi'_r - \xi''_r, x_{r+1} - x'_r \rangle \\
& \leq \frac{1 - \tau}{\beta_r} \|x_{r+1} - x'_r\|^2 + \gamma_r \beta_r \langle x_{r+1} - x'_r, x_{r+1} - x'_r \rangle - \frac{1 - \tau}{\beta_r} \langle v''_r, x_{r+1} - x'_r \rangle \\
& \leq \frac{1 - \tau}{\beta_r} \|x_{r+1} - x'_r\|^2 + \langle \nabla h_2(x'_r) - \nabla h_2(x''_{r-1}), x_{r+1} - x'_r \rangle \\
& + \frac{1 - \tau}{2\beta_r} \|x''_{r-1}\|^2 - \frac{1 - \tau}{2\beta_r} \|x'_r - x''_{r-1}\|^2 - \frac{1 - \tau}{\beta_r} \|v''_r\|^2 + \gamma_r \beta_r \langle x_{r+1} - x'_r, x_{r+1} - x'_r \rangle \\
& \leq \frac{1 - \tau}{2\beta_r} \|x_{r+1} - x'_r\|^2 + \gamma_r \beta_r \langle x_{r+1} - x'_r, x_{r+1} - x'_r \rangle \\
& \leq \frac{1 - \tau}{2\beta_r} \|x_{r+1} - x'_r\|^2 + \frac{\gamma_r}{2} \|x_{r+1}\|^2 - \frac{\gamma_r}{2} \|x''_{r-1}\|^2 + \left(\frac{\gamma_{r-1} - \gamma_r}{2}\right) \|x_{r+1}\|^2 \\
& \leq \frac{1 - \tau}{2\beta_r} \|x_{r+1} - x'_r\|^2 + \frac{\gamma_r}{2} \|x_{r+1}\|^2 - \frac{\gamma_r}{2} \|x''_{r-1}\|^2 + \left(\frac{\gamma_{r-1} - \gamma_r}{2}\right) \|x_{r+1}\|^2 \\
& \leq \frac{1 - \tau}{\beta_r} \|x''_{r+1}\|^2 - \frac{1 - \tau}{2\beta_r} \|x''_{r-1}\|^2.
\end{align*}
\]
where in (a) we use the optimality condition of \( \lambda \)-problem, i.e.,
\[
\xi'_{r+1} - \nabla h_2(x'_r) + \frac{1 - \tau}{\beta_r} (x_{r+1} - x'_r) + \gamma_r x'_r = 0,
\]
and in (b) we substitute
\[
\langle \xi'_{r+1} - \xi'_r, x_{r+1} - x'_r \rangle = \langle \nabla h_2(x'_r) - \nabla h_2(x''_{r-1}), x_{r+1} - x'_r \rangle - \frac{1 - \tau}{\beta_r} \left( x_{r+1} - x'_r - (x'_r - x''_{r-1}) \right),
\]
and in (c) we use quadrilateral identity (38), and in (d) we use Young’s inequality with parameter \( \beta_r \), i.e.,
\[
\langle \nabla h_2(x'_r) - \nabla h_2(x''_{r-1}), x_{r+1} - x'_r \rangle \\
\leq \langle \nabla h_2(x'_r) - \nabla h_2(x''_{r-1}), v''_{r+1} + x''_{r-1} - x''_{r-1} \rangle \\
= \left\langle \frac{1 - \tau}{\beta_r} (x''_{r-1} - x''_{r-1}), v''_{r+1} + x''_{r-1} - x''_{r-1} \right\rangle \\
\leq \frac{1 - \tau}{2\beta_r} \|x''_{r-1}\|^2 + \frac{1 - \tau}{2\beta_r} \|v''_{r+1}\|^2 - \frac{1 - \tau}{\beta_r} \|x''_{r-1}\|^2,
\]
Combining the above two cases (i.e., (50) and (57)), we have
\[
F_{\beta_r}(x_{r+1}, \lambda_{r+1}) - F_{\beta_r}(x_{r+1}, \lambda_r) \\
\leq \frac{(1 - \tau)^2}{2\beta_r} \|\lambda_{r+1} - \lambda_{r-1}\|^2 + \frac{(1 - \tau)\beta_r L^2_\beta}{2} \|x_{r+1} - x_r\|^2 \\
+ \frac{(1 - \tau)^2}{\beta_r} \|\lambda_{r+1} - \lambda_r\|^2 + \frac{(1 - \tau)\gamma_r}{2} \|x_{r+1}\|^2 - \frac{(1 - \tau)\gamma_{r-1}}{2} \|\lambda_r\|^2 + (1 - \tau) \left(\frac{\gamma_{r-1} - \gamma_r}{2}\right) \|\lambda_{r+1}\|^2
\]
where we use the facts that \( \|\lambda'_{r+1} - \lambda'_r\|^2 + \|\lambda'_{r+1} - \lambda'_r\|^2 = \|\lambda_{r+1} - \lambda_r\|^2, \|\lambda'_{r+1}\|^2 + \|\lambda'_{r+1}\|^2 = \|\lambda_{r+1}\|^2, \|\lambda'_r\|^2 + \|\lambda'_r\|^2 = \|\lambda_r\|^2 \) and drop the negative terms.
Note that from (31) we have

$$F_{\beta_{r+1}}(x_{r+1}, \lambda_{r+1}) \leq F_{\beta_r}(x_{r+1}, \lambda_{r+1}) + (\beta_{r+1} - \beta_r) \|g(x_{r+1})\|^2 + \left(\frac{1}{\beta_{r+1}} - \frac{1}{\beta_r}\right) (1 - \tau)^2 \|\lambda_{r+1}\|^2.$$  \hfill (64)

where we use the following fact

$$\sum_{i \in S_r} \frac{\beta_{r+1}}{2} g_{i}^2(x_{r+1}) - \frac{\beta_r}{2} g_{i}^2(x_{r+1}) = \frac{\beta_{r+1} - \beta_r}{2} \|g_1(x_{r+1})\|^2.$$  \hfill (65)

Combining (63) and (64), we can obtain the changes of $F_{\beta_r}$ after one round update of $x$ and $\lambda$, i.e.,

$$F_{\beta_{r+1}}(x_{r+1}, \lambda_{r+1}) - F_{\beta_r}(x_r, \lambda_r) \leq \frac{1 - \tau}{2\beta_r} \|\lambda_r - \lambda_{r-1}\|^2 - \left(\frac{1 - \tau}{2\alpha_r} - \frac{(1 - \tau)\beta_r^2}{2}\right) \|x_{r+1} - x_r\|^2$$

$$+ \frac{1 - \tau}{\beta_r} \|\lambda_{r+1} - \lambda_r\|^2 + (\beta_{r+1} - \beta_r) \|g_1(x_{r+1})\|^2 + \left(\frac{1}{\beta_{r+1}} - \frac{1}{\beta_r}\right) (1 - \tau)^2 \|\lambda_{r+1}\|^2$$

$$+ \frac{(1 - \tau)\gamma_r}{2} \|\lambda_{r+1}\|^2 - \frac{(1 - \tau)\gamma_{r-1}}{2} \|\lambda_r\|^2 + (1 - \tau) \left(\frac{\gamma_r - \gamma_{r-1}}{2}\right) \|\lambda_{r+1}\|^2,$$  \hfill (66)

which gives the desired result as $0 < \tau < 1$. \hfill \Box

**B.2. Recursion of the Size of the Difference between Two Successive Dual Variables**

**Lemma 6.** Suppose that Assumption 1–Assumption 2 hold. If the iterates $\{x_r, \lambda_r, \forall r\}$ are generated by GDPA, then we have

$$\frac{2\theta(1 - \tau)}{\beta_{r+1}^r} \|\lambda_{r+1} - \lambda_r\|^2 - \frac{2\theta}{\beta_r} \left(\frac{\gamma_r - \gamma_{r-1}}{\gamma_{r-1}} - 1\right) \|\lambda_{r+1}\|^2$$

$$\leq \frac{2\theta(1 - \tau)}{\beta_{r-1}^r} \|\lambda_r - \lambda_{r-1}\|^2 - \frac{2\theta}{\beta_{r-1}^r} \left(\frac{\gamma_{r-2}}{\gamma_{r-1}} - 1\right) \|\lambda_r\|^2 + \frac{2\theta}{\beta_r} \left(\frac{\gamma_{r-2}}{\gamma_{r-1}} - \frac{\gamma_{r-1}}{\gamma_{r-1}}\right) \|\lambda_{r+1}\|^2$$

$$- \frac{2\theta}{\beta_r} \|\lambda_{r+1} - \lambda_r\|^2 + \frac{2\theta L^2}{\gamma_{r+1}} \|x_{r+1} - x_r\|^2 + \frac{4\theta}{\tau} \left(\frac{1}{\beta_{r-1}^r} - \frac{1}{\beta_r}\right) \langle \lambda_r - \lambda_{r-1}, \lambda_{r+1} - \lambda_r\rangle$$

$$+ \frac{2\theta}{\tau} \left(\frac{1}{\beta_r} - \frac{1}{\beta_{r-1}^r}\right) \|\lambda_r - \lambda_{r-1}\|^2 + \frac{2\theta}{\beta_{r-1}^r} \left(\frac{\gamma_{r-2}}{\gamma_{r-1}} - 1\right) \|\lambda_r\|^2.$$  \hfill (67)

**Proof.** [Part I] From the optimality condition of $\lambda$-problem at the $r + 1$th iteration, we have

$$- (g_1(x_{r+1}) - \frac{1 - \tau}{\beta_r} (\lambda_{r+1} - \lambda_r)) - \gamma_{r+1} \lambda_{r+1} - \lambda') \leq 0, \forall \lambda' \geq 0.$$  \hfill (68)

Similarly, from the optimality condition of $\lambda$-problem at the $r$th iteration, we have

$$- (g_1(x_{r}) - \frac{1 - \tau}{\beta_{r-1}} (\lambda_{r} - \lambda_{r-1})) - \gamma_{r} \lambda_{r} - \lambda') \geq 0, \forall \lambda' \geq 0.$$  \hfill (69)

Plugging $\lambda' = \lambda_{r+1}$ in (68), $\lambda' = \lambda_{r+1}$ in (69) and combining them together, we can get

$$\frac{1 - \tau}{\beta_{r+1}} (\lambda_{r+1} - \lambda_r) + (\gamma_{r+1} \lambda_{r+1} - \gamma_{r} \lambda_{r})$$

$$\leq (g(x_{r+1}) - g(x_r)) + \left(\frac{1}{\beta_{r+1}} - \frac{1}{\beta_r}\right) (\lambda_{r+1} - \lambda_{r-1}) \lambda_{r+1} - \lambda_r).$$  \hfill (70)
In the following, we will use this inequality to analyze the recurrence of the size of the difference between two consecutive iterates. First, we have

\[ \langle \gamma_r \lambda_{r+1} - \gamma_{r-1} \lambda_r, \lambda_{r+1} - \lambda_r \rangle = \langle \gamma_r \lambda_{r+1} - \gamma_r \lambda_r, \gamma_r \lambda_{r-1} - \gamma_{r-1} \lambda_r \rangle = \gamma_r \langle \lambda'_{r+1} - \lambda'_r \rangle + \gamma_r - \gamma_{r-1} \langle \lambda_r, \lambda_{r+1} - \lambda_r \rangle \]

\[ \leq 2 \beta_r \left( \frac{1}{2} \right) \| \lambda_{r+1} - \lambda_r \|^2 \frac{\lambda_r - \lambda_{r-1}}{2} \| \lambda_r - \lambda_{r-1} \|^2 \frac{\lambda_{r-1} - \lambda_r}{2} \| \lambda_r - \lambda_{r-1} \|^2 \]

\[ + \langle \gamma_r (x_{r+1}) - g_1(x_r), \lambda_{r+1} - \lambda_r \rangle + \left( \frac{1}{\beta_{r-1} - 1} \right) \| \lambda_{r+1} - \lambda_r \|^2 \]

\[ \leq \frac{1}{2} \beta_r \left( \frac{1}{2} \right) \| \lambda_r - \lambda_{r-1} \|^2 \frac{\lambda_r - \lambda_{r-1}}{2} \| \lambda_{r-1} - \lambda_r \|^2 \frac{\lambda_{r-1} - \lambda_r}{2} \| \lambda_{r-1} - \lambda_r \|^2 \]

\[ + \langle \gamma_r (x_{r+1}) - g_1(x_r), \lambda_{r+1} - \lambda_r \rangle + \left( \frac{1}{\beta_{r-1} - 1} \right) \| \lambda_{r+1} - \lambda_r \|^2 \]

Next, substituting (72) and (73) into (70), we have

\[ \frac{1}{2} \beta_r \left( \frac{1}{2} \right) \| \lambda_{r+1} - \lambda_r \|^2 \frac{\lambda_r - \lambda_{r-1}}{2} \| \lambda_{r-1} - \lambda_r \|^2 \frac{\lambda_{r-1} - \lambda_r}{2} \| \lambda_{r-1} - \lambda_r \|^2 \]

\[ + \langle \gamma_r (x_{r+1}) - g_1(x_r), \lambda_{r+1} - \lambda_r \rangle + \left( \frac{1}{\beta_{r-1} - 1} \right) \| \lambda_{r+1} - \lambda_r \|^2 \]

where \( a \) is true because \( 0 < \gamma_r < \gamma_{r-1} \), in \( b \) we use Young's inequality.
Multiplying by $4\theta$ and dividing by $\tau$ on the both sides of the above equation, we can get

$$
\frac{2\theta(1 - \tau)}{\beta r^2} \|x_{r+1}' - x_r'\|^2 - \frac{2\theta}{\beta r} \left(\frac{\gamma r - 1}{\gamma r - 1} - 1\right) \|x_{r+1}'\|^2 \\
\leq \frac{2\theta(1 - \tau)}{\beta r^2} \|x'_r - x_{r-1}'\|^2 - \frac{2\theta}{\beta r} \left(\frac{\gamma r - 2}{\gamma r - 1} - 1\right) \|x'_r\|^2 + \frac{2\theta L_g^2}{\gamma r^2} \|x_{r+1} - x_r\|^2 \\
+ \frac{4\theta}{\tau} \left(\frac{1}{\beta r - 1} - \frac{1}{\beta r}\right) \langle x'_r - x_{r-1}', x_{r+1}' - x'_r\rangle
$$

(78)

where in (a) we use

$$
\frac{2\theta}{\beta r^2} \|x'_r - x_{r-1}'\|^2 = \left(\frac{2\theta}{\beta r - 1} - \frac{2\theta}{\beta r - 1^2}\right) \|x'_r - x_{r-1}'\|^2
$$

(81)

and $0 < \tau < 1$.

[Part II] Similarly, from the optimality condition of $\lambda$-problem at the $r + 1$ iteration, we have

$$
-\langle \nabla h_2(x'_r) - \frac{1-\tau}{\beta r} (x_{r+1}' - x_r') - \gamma_r x_{r+1} - x_r'\rangle \leq 0, \forall x'_r \geq 0.
$$

(83)

Similarly, from the optimality condition of $\lambda$-problem at the $r$th iteration, we have

$$
-\langle \nabla h_2(x'_{r-1}) - \frac{1-\tau}{\beta r - 1} (x'_{r-1} - x'_{r-1}) - \gamma_{r-1} x_{r-1} - x'_r\rangle \geq 0, \forall x'_r \geq 0.
$$

(84)

Following (70) to (75), we have

$$
\frac{1 - \tau}{2\beta r} \|x'_{r+1} - x_{r+1}'\|^2 - \frac{\gamma r - 1 - \gamma_r}{2} \|x_{r+1}'\|^2 \\
\leq \frac{1 - \tau}{2\beta r} \|x'_r - x_{r-1}'\|^2 - \frac{\gamma r - 1 - \gamma_r}{2} \|x'_r\|^2 + \frac{\gamma r + \gamma r - 1 - \gamma_r}{2} \|x'_{r+1} - x'_r\|^2 + \left(\frac{1}{\beta r - 1} - \frac{1}{\beta r}\right) \langle x'_r - x_{r-1}', x_{r+1}' - x'_r\rangle
$$

+ \langle \nabla h_2(x'_{r+1}) - \nabla h_2(x'_{r-1}), x'_{r+1} - x'_r\rangle - \frac{1}{2\beta r} \|\nabla x'_{r+1}\|^2
$$

(85)

where in (a) we use (62) again.
Following (78) to (82), we have

\[
\frac{2\vartheta(1 - \tau)}{\beta_r \tau} \| x_{r+1} - x_r \|^2 - \frac{2\vartheta}{\beta_r} \left( \frac{\gamma_{r-1} - 1}{\gamma_r} \right) \| x_{r+1} \|^2 \\
\leq \frac{2\vartheta(1 - \tau)}{\beta_{r+1} \tau} \| \lambda'_{r+1} - \lambda'_{r-1} \|^2 - \frac{2\vartheta}{\beta_{r+1}} \left( \frac{\gamma_{r-2} - 1}{\gamma_{r-1}} \right) \| \lambda'_{r+1} \|^2 + \frac{2\vartheta}{\beta_{r+1}} \left( \frac{\gamma_{r-2} - \gamma_{r-1}}{\gamma_{r-1}} \right) \| \lambda'_{r} \|^2 \\
- \frac{2\vartheta}{\beta_r} \| \lambda'_{r+1} - \lambda'_{r} \|^2 + \frac{4\vartheta}{\tau} \left( \frac{1}{\beta_{r+1}} - \frac{1}{\beta_r} \right) \langle \lambda'_{r+1}, \lambda'_{r-1} - \lambda'_{r} \rangle \\
+ \frac{2\vartheta}{\tau} \left( \frac{1}{\beta_r} - \frac{1}{\beta_{r+1}} \right) \| x_r - x_{r-1} \|^2 + \frac{2\vartheta}{\beta_{r+1}} \left( \frac{\gamma_{r-2} - 1}{\gamma_{r-1}} \right) \| \lambda_{r+1} \|^2.
\] (87)

Merging (80) and (87) gives (67) based on the definitions of \( \lambda' \) and \( \lambda \) shown in (33).

### B.3. Construction of a Potential Function

**Lemma 7.** Suppose that Assumption 1–Assumption 3 hold and the iterates \( \{x_r, \lambda_r, \forall r\} \) are generated by GDPA. If the step-sizes satisfy

\[
\frac{1}{4\alpha_r} > \frac{(1 - \tau) \beta_r L_{\alpha, r}^2}{2} + \frac{2\vartheta L_{\alpha, r}^2}{\gamma_r \tau},
\] (88)

and \( \vartheta > 1 \), then, we have

\[
\frac{1}{2\beta_r} \| \lambda_{r+1} - \lambda_r \|^2 + \frac{1}{4\alpha_r} \| x_{r+1} - x_r \|^2 \\
\leq P_r - P_{r+1} + \frac{2\vartheta}{\beta_r} \left( \frac{\gamma_{r-2} - \gamma_{r-1}}{\gamma_{r-1}} \right) \| \lambda_r \|^2 + \frac{4\vartheta}{\tau} \left( \frac{1}{\beta_{r+1}} - \frac{1}{\beta_r} \right) \langle \lambda_r - \lambda_{r-1}, \lambda_{r+1} - \lambda_r \rangle \\
+ \left( \frac{1}{2} + \frac{2\vartheta}{\tau} \right) \left( \frac{1}{\beta_r} - \frac{1}{\beta_{r+1}} \right) \| \lambda_r - \lambda_{r-1} \|^2 + \frac{2\vartheta}{\beta_{r+1}} \left( \frac{2}{\beta_{r+1}} - \frac{1}{\beta_r} \right) \left( \frac{\gamma_{r-2} - 1}{\gamma_{r-1}} \right) \| \lambda_r \|^2 \\
+ (\beta_{r+1} - \beta_r) \| g_1(x_{r+1}) \|^2 + \left( \frac{1}{\beta_r} - \frac{1}{\beta_{r+1}} \right) \| \lambda_{r+1} \|^2 + \left( \frac{\gamma_{r-1} - \gamma_r}{2} \right) \| \lambda_r \|^2
\] (89)

where the potential function is defined as

\[
P_r \triangleq F_{\beta_r}(x_r, \lambda_r) + (1 - \tau) \left( \frac{1}{2\beta_{r+1}} + \frac{2\vartheta}{\beta_{r+1} \tau} \right) \| \lambda_r - \lambda_{r-1} \|^2 - \frac{(1 - \tau) \gamma_{r-1}}{2} \| \lambda_r \|^2 - \frac{2\vartheta}{\beta_{r+1}} \left( \frac{\gamma_{r-2} - \gamma_{r-1}}{\gamma_{r-1}} \right) \| \lambda_r \|^2.
\] (90)
A Single-Loop Gradient Descent and Perturbed Ascent Algorithm for Nonconvex Functional Constrained Optimization

Proof. Combining (42) in Lemma 5 and (67) in Lemma 6, we have

\[
\begin{align*}
F_{\beta_{r+1}}(x_{r+1}, \lambda_{r+1}) &+ \left( \frac{1 - \tau}{2\beta_{r}} + 2\theta (1 - \tau) \right) \| \lambda_{r+1} - \lambda_r \|^2 - \frac{(1 - \tau)\gamma_r}{2} \| \lambda_{r+1} \|^2 - \frac{2\theta}{\beta_r} \left( \frac{\gamma_{r-1}}{\gamma_r - 1} \right) \| \lambda_{r+1} \|^2 \\
\leq & F_{\beta_r}(x_r, \lambda_r) + \left( \frac{1 - \tau}{2\beta_{r-1}} + 2\theta (1 - \tau) \right) \| \lambda_r - \lambda_{r-1} \|^2 - \frac{(1 - \tau)\gamma_{r-1}}{2} \| \lambda_r \|^2 - \frac{2\theta}{\beta_{r-1}} \left( \frac{\gamma_{r-2}}{\gamma_{r-1} - 1} \right) \| \lambda_r \|^2 \\
& - \frac{1}{2\beta_{r-1}} \| \lambda_{r+1} - \lambda_r \|^2 - \left( \frac{1 - \tau}{2\alpha_r} - \frac{(1 - \tau)\beta_{r-1}L_2^2}{\gamma_{r-1}} \right) \| x_{r+1} - x_r \|^2 \\
& + \frac{2\theta}{\beta_{r}} \left( \frac{\gamma_{r-2}}{\gamma_{r-1} - 1} \right) \| \lambda_r - \lambda_{r-1} \|^2 + \frac{4\theta}{\tau} \left( \frac{1}{\beta_{r-1}} - \frac{1}{\beta_r} \right) \langle \lambda_r - \lambda_{r-1}, \lambda_{r+1} - \lambda_r \rangle \\
& + \left( \frac{1 - \tau}{2} + \frac{2\theta}{\tau} \right) \left( \frac{1}{\beta_{r-1}} - \frac{1}{\beta_r} \right) \| \lambda_r - \lambda_{r-1} \|^2 + \left( \frac{2\theta}{\beta_{r-1}} - \frac{2\theta}{\beta_r} \right) \left( \frac{\gamma_{r-2}}{\gamma_{r-1} - 1} \right) \| \lambda_r \|^2 \\
& + (\beta_{r+1} - \beta_r) \| g_1(x_{r+1}) \|^2 + \left( \frac{1}{\beta_{r+1}} - \frac{1}{\beta_r} \right) (1 - \tau)^2 \| \lambda_{r+1} \|^2 + (1 - \tau) \left( \frac{\gamma_{r-1} - \gamma_r}{2} \right) \| \lambda_{r+1} \|^2
\end{align*}
\]

(91)

where we use the following fact that

\[
\frac{1}{2\beta_r} \| \lambda_r - \lambda_{r-1} \|^2 \leq \frac{1}{2\beta_{r-1}} \| \lambda_r - \lambda_{r-1} \|^2 - \frac{1}{2\beta_{r-1}} \| \lambda_r - \lambda_{r-1} \|^2 + \frac{1}{2\beta_{r}} \| \lambda_r - \lambda_{r-1} \|^2 \\
\leq \frac{1}{2\beta_{r-1}} \| \lambda_r - \lambda_{r-1} \|^2 + \frac{1}{2} \left( \frac{1}{\beta_{r-1}} - \frac{1}{\beta_r} \right) \| \lambda_r - \lambda_{r-1} \|^2,
\]

(92)

and note that term \( \frac{(1 - \tau)}{2\alpha_r} \| \lambda_{r+1} - \lambda_r \|^2 \) has been dominated by the descent term as \( \theta > 1 \), i.e., \(- \frac{2\theta}{\beta_r} \| \lambda_{r+1} - \lambda_r \|^2 \).

As \( 0 < \tau < 1 \), we can rewrite (91) as

\[
P_{r+1} \leq P_r - \left( \frac{1}{2\alpha_r} - \frac{(1 - \tau)\beta_{r-1}L_2^2}{\gamma_{r-1}} \right) \| x_{r+1} - x_r \|^2 \\
- \frac{1}{2\beta_r} \| \lambda_{r+1} - \lambda_r \|^2 + \frac{2\theta}{\beta_r} \left( \frac{\gamma_{r-2}}{\gamma_{r-1} - 1} \right) \| \lambda_r \|^2 \\
+ \frac{4\theta}{\tau} \left( \frac{1}{\beta_{r-1}} - \frac{1}{\beta_r} \right) \langle \lambda_r - \lambda_{r-1}, \lambda_{r+1} - \lambda_r \rangle \\
+ \left( \frac{1}{2} + \frac{2\theta}{\tau} \right) \left( \frac{1}{\beta_{r-1}} - \frac{1}{\beta_r} \right) \| \lambda_r - \lambda_{r-1} \|^2 + \theta \left( \frac{2}{\beta_{r-1}} - \frac{2}{\beta_r} \right) \left( \frac{\gamma_{r-2}}{\gamma_{r-1} - 1} \right) \| \lambda_r \|^2 \\
+ (\beta_{r+1} - \beta_r) \| g_1(x_{r+1}) \|^2 + \left( \frac{1}{\beta_{r+1}} - \frac{1}{\beta_r} \right) \| \lambda_{r+1} \|^2 + \left( \frac{\gamma_{r-1} - \gamma_r}{2} \right) \| \lambda_{r+1} \|^2.
\]

(93)

Using (88), we can obtain the desired result as shown in (89).

\[\square\]

C. Optimality Gap

C.1. Proof of Lemma 2

Proof. Based on the definition of \( G(x, \lambda) \) in (15) and the update rule of GDPA in (13), we can have the upper bound of \( \| G(x_r, \lambda_r) \| \) in terms of \( \| x_{r+1} - x_r \|, \| \lambda_{r+1} - \lambda_r \|, \) and \( \| \lambda_{r+1} \| \).

First Step. Notice that \( \beta_r g_1(x_r) + (1 - \tau)\lambda_r = 0 \), \( \forall i \in S_r \), and \( \lambda_r \geq 0 \), meaning that \( \beta_r g_1(x_r) \leq 0 \), i.e., \( \beta_r g_1(x_r) \leq -(1 - \tau)\lambda_i \). So, we have \( \lambda_i + \beta_r g_1(x_r) \leq \tau \lambda_i, \forall i \in S_r \). Due to non-expansiveness of the projection operator, we have

\[
\| x'_{r+1} - \text{proj}_{\geq 0} (x_r + \beta_r g_2(x_r)) \| \leq \tau \| x_r \| \stackrel{(a)}{=} \tau \| x_{r+1} - x_r \|,
\]

(94)
where
\[
[g_2(x_r)]_i = \begin{cases} 
g_i(x_r), & \text{if } i \in \mathcal{I}_r; \\
0, & \text{otherwise}, \end{cases}
\] (95)

and in (a) we use the fact $\overline{x}'_{r+1} = 0$.

**Second Step.** Then, we can have
\[
\begin{align*}
\|G(x_r, \lambda_r)\| & \leq \frac{1}{\alpha_r} \|x_{r+1} - x_r\| + \frac{1}{\alpha_r} \|x_{r+1} - \text{proj}_X (x_r - \alpha_r \nabla_x L(x_r, \lambda_r))\| \\
& \quad + \frac{1}{\beta_r} \|\lambda_{r+1} - \lambda_r\| + \frac{1}{\beta_r} \|\lambda_{r+1} - \text{proj}_{\geq 0} (\lambda_r + \beta_r \nabla \lambda L(x_r, \lambda_r))\| \\
\overset{(a)}{\leq} & \frac{1}{\alpha_r} \|x_{r+1} - x_r\| \\
& \quad + \frac{1}{\alpha_r} \|\text{proj}_X (x_{r+1} - \alpha_r (\nabla_x f(x_r) + J^T(x_r) [(1 - \tau) \lambda_r + \beta_r g(x_r)] + \frac{1}{\alpha_r} (x_{r+1} - x_r)) \| \\
& \quad - \text{proj}_X (x_r - \alpha_r (\nabla_x f(x_r) + J^T(x_r) \lambda_r)) \\
& \quad + \frac{1}{\beta_r} \|\lambda_{r+1} - \lambda_r\| \\
& \quad + \frac{1}{\beta_r} \|\text{proj}_{\geq 0} (\lambda_{r+1}' + \beta_r (g_1(x_{r+1}) - \frac{1}{\beta_r} (\lambda_{r+1}' - \lambda_{r+1}' - \gamma_r \lambda_{r+1}'))) - \text{proj}_{\geq 0} (\lambda_r + \beta_r g_1(x_r))\| \\
& \quad + \frac{1}{\beta_r} \|\overline{x}'_{r+1} - \text{proj}_{\geq 0} (\overline{x}' + \beta_r g_2(x_r))\| \\
\overset{(b)}{\leq} & \frac{3}{\alpha_r} \|x_{r+1} - x_r\| + \frac{3 + \tau}{\beta_r} \|\lambda_{r+1} - \lambda_r\| + \gamma_r \|\lambda_{r+1}\| + \|g(x_{r+1}) - g(x_r)\| \\
& \quad + U_j \|(1 - \tau) \lambda_r + \beta_r g(x_r)]_+ - \lambda_r\| \\
\overset{(c)}{\leq} & \left(3 + \frac{L_g}{\alpha_r}\right) \|x_{r+1} - x_r\| + \frac{3 + \tau}{\beta_r} \|\lambda_{r+1} - \lambda_r\| + \gamma_r \|\lambda_{r+1}\| + U_j \|(1 - \tau) \lambda_r + \beta_r g(x_r)]_+ - \lambda_r\|
\end{align*}
\] (96)

where in (a) we apply the optimality condition of the subproblems, i.e.,
\[
x_{r+1} = \text{proj}_X \left( x_{r+1} - \alpha_r \left( \nabla_x f(x_r) + J^T(x_r) [(1 - \tau) \lambda_r + \beta_r g(x_r)]_+ + \frac{1}{\alpha_r} (x_{r+1} - x_r) \right) \right),
\] (99a)
\[
\lambda_{r+1}' = \text{proj}_{\geq 0} \left( \lambda_{r+1}' + \beta_r \left( g_1(x_{r+1}) - \frac{1}{\beta_r} (\lambda_{r+1}' - \lambda_{r+1}' - \gamma_r \lambda_{r+1}'))) \right),
\] (99b)

and the fact that $\sqrt{\|x\|^2 + \|y\|^2} \leq \|x\| + \|y\|$, in (b) we use the triangle inequality, non-expansiveness of the projection operator, (94), and (c) is true due to the Lipschitz continuity.

**Third Step.**

To quantify term $\|(1 - \tau) \lambda_r + \beta_r g(x_r)]_+ - \lambda_r\|$, we first have
\[
\|[(1 - \tau) \overline{x}' + \beta_r g_2(x_r)]_+ - \overline{x}'\| \overset{(1)}{=} \|\overline{x}'\| = \|\overline{x}'_{r+1} - \overline{x}'_r\|,
\] (100)

since $\overline{x}'_{r+1} = 0$.

Second, for $i \in \mathcal{S}_r$, we have the following two cases:
1) when \((1 - \tau)[\lambda_i] + \beta_r g_i(x_{r+1}) \geq 0\), then \((1 - \tau)[\lambda_i] + \beta_r g_i(x_{r+1}) = [\lambda_{r+1}]_i\), so we have

\[
||((1 - \tau)[\lambda_i] + \beta_r g_i(x_r))_+ - [\lambda_i]|| \leq ||(1 - \tau)[\lambda_i] + \beta_r g_i(x_r + 1) + \beta_r g_i(x_r) - \beta_r g_i(x_{r+1})_+ - [\lambda_i]|| (101)
\]

\[
\leq ||(1 - \tau)[\lambda_i] + \beta_r g_i(x_r + 1) + \beta_r g_i(x_r) - \beta_r g_i(x_{r+1}) - [\lambda_i]|| (102)
\]

\[
\leq |\beta_r g_i(x_r) - \beta_r g_i(x_{r+1})| + |(1 - \tau)[\lambda_i] + \beta_r g_i(x_{r+1}) - [\lambda_i]| (103)
\]

\[
= |\beta_r g_i(x_r) - \beta_r g_i(x_{r+1})| + |[\lambda_{r+1}]_i - [\lambda_i]| (104)
\]

where in \((a)\) we use non-expansiveness of the projection operator, in \((b)\) we use the triangle inequality;

2) when \((1 - \tau)[\lambda_i] + \beta_r g_i(x_{r+1}) < 0\), then \([\lambda_{r+1}]_i = 0\), and based on the definition of \(\lambda_r\) we have \(\beta_r g_i(x_{r+1}) - g_i(x_r) \geq 0\), which gives

\[
[(1 - \tau)[\lambda_i] + \beta_r g_i(x_r) - \beta_r g_i(x_{r+1} + \beta_r g_i(x_{r+1})_+ - \beta_r g_i(x_r), (105)
\]

so we have

\[
||((1 - \tau)[\lambda_r]_+ + \beta_r g_i(x_r)) - [\lambda_r]|| \leq ||(1 - \tau)[\lambda_r]_+ + \beta_r g_i(x_r + 1) + \beta_r g_i(x_r) - [\lambda_r]|| (106)
\]

\[
\leq |\beta_r g_i(x_r + 1) - \beta_r g_i(x_r) - [\lambda_r]| (107)
\]

\[
\leq |\beta_r g_i(x_{r+1}) - \beta_r g_i(x_r)| + |[\lambda_{r+1}]_i - [\lambda_i]|, (108)
\]

where in \((a)\) we use \([\lambda_{r+1}]_i = 0\) in this case, in \((b)\) we use the triangle inequality.

Combining the above two cases, we can get

\[
||((1 - \tau)[\lambda_r]_+ + \beta_r g_i(x_r)) - [\lambda_r]|| \leq \beta_r L_g ||x_{r+1} - x_r|| + ||[\lambda_{r+1}]_i - [\lambda_i]| (109)
\]

where we use the Lipschitz continuity of function \(g()\).

Combining \((100)\) and \((109)\) gives rise to

\[
||(1 - \tau)[\lambda_r] + \beta_r g(x_r))_+ - [\lambda_r]||^2 \leq \beta_r L_g ||x_{r+1} - x_r||^2 + ||[\lambda_{r+1}]_i - [\lambda_i]|^2 (110)
\]

where we use the fact \(||x||^2 \leq 2\||y||^2 + 2\||z||^2\) when \(||x|| \leq ||y|| + ||z||\).

Towards this end, we have

\[
\mathcal{G}(x_r, \lambda_r) \leq 4 \left( \frac{3}{\alpha_r} + L_g \right) ||x_{r+1} - x_r||^2 + 4 \left( \frac{3 + \tau}{\beta_r} \right) ||\lambda_{r+1} - \lambda_r||^2 + 4 \gamma_r^2 ||\lambda_{r+1}||^2 (111)
\]

\[
\leq 4 \left( \frac{3}{\alpha_r} + L_g \right)^2 + 2 \frac{L_g^2 \beta_r^2}{\lambda_{r+1} - \lambda_r}^2 + 3 ||\lambda_{r+1} - \lambda_r||^2 + 4 \gamma_r^2 ||\lambda_{r+1}||^2.
\]

C.2. Upper bound of dual variable
Lemma 8. Suppose that Assumption 4 holds. If the iterates \( \{x_r, \lambda_r, \forall r\} \) are generated by GDPA, where the step-sizes are chosen according to (17), then we have

\[
\|\lambda_{r+1}\|^2 \leq \frac{G (1 + \frac{1}{\theta'}) r^{2/3}}{1 - \eta} \sim O(r^{2/3})
\]

where \( 0 < \eta < 1 \) and \( \theta' < 1/(1 - \tau)^2 - 1 \).

Proof. Recall (26). Let \( \lambda_{r+1}^g \) be a vector whose the \( i \)th entry is

\[
\lambda_{r+1}^g_i = \begin{cases} 
\lambda_{r+1}, & \text{if } i \in A_{r+1} \cap S_r; \\
0, & \text{otherwise}
\end{cases}
\]

where \( A_{r+1} \triangleq \{i | \hat{g}_i(x_{r+1}) > 0\} \).

Based on (13b), we have

\[
\|\lambda_{r+1}^g\|^2 \leq (1 + \theta')(1 - \tau)^2\|\lambda_r^g\|^2 + \left(1 + \frac{1}{\theta'}\right) \beta_r^2 \|g_+ (x_{r+1})\|^2
\]

where notation \( \lambda_r^g \) means that the \( i \)th entry of \( \lambda_r^g \) is

\[
\lambda_{r+1}^g_i = \begin{cases} 
\lambda_r, & \text{if } i \in A_{r+1} \cap S_r; \\
0, & \text{otherwise}
\end{cases}
\]

If Assumption 4 holds, i.e., \( \|g_+ (x_{r+1})\|^2 \leq G \), then from (17), we have

\[
\|\lambda_{r+1}^g\|^2 \leq (1 + \theta')(1 - \tau)^2\|\lambda_r^g\|^2 + \left(1 + \frac{1}{\theta'}\right) Gr^{2/3}.
\]

Here, we can choose \( \theta' < 1/(1 - \tau)^2 - 1 \) so that \( (1 + \theta')(1 - \tau)^2 \triangleq \eta' < 1 \). Then, we have

\[
\|\lambda_{r+1}^g\|^2 \leq \eta'\|\lambda_r^g\|^2 + \left(1 + \frac{1}{\theta'}\right) Gr^{2/3}.
\]

Note that

\[
[\lambda_{r+1}], \leq (1 - \tau)[\lambda_r], \forall i \in \overline{A}_{r+1} \cap S_r,
\]

\[
[\lambda_{r+1}] = 0, \forall i \in \overline{S}_r.
\]

Combining (116), (27) and (118), we have

\[
\|\lambda_{r+1}\|^2 \leq \eta\|\lambda_r\|^2 + \left(1 + \frac{1}{\theta'}\right) Gr^{2/3}
\]

\[
\leq \eta^2\|\lambda_{r-1}\|^2 + \eta \left(1 + \frac{1}{\theta'}\right) Gr^{2/3} + \left(1 + \frac{1}{\theta'}\right) Gr^{2/3}
\]

\[
\leq \frac{G (1 + \frac{1}{\theta'}) r^{2/3}}{1 - \eta}
\]

where \( \eta \triangleq \max\{(1 - \tau)^2, \eta'\} \).
C.3. Regularity Condition: Proof of Lemma 3

Proof. Recall the fact that when \(g(x_{r+1}) \leq 0\), we know from (13b) that

\[
[\lambda_{r+1}]_i \leq (1 - \tau)[\lambda_r]_i, \quad \forall i \in A_{r+1} \cap S_r. \tag{122}
\]

Due to the nonnegativity of \(\lambda_r\) and \(\tau \in (0, 1)\). This implies that the size of the dual variable \([\lambda_{r+1}]_i\) is shrunk. Also, note that \([\lambda_{r+1}]_i = 0, i \in S_r\).

Upon the above results, we only need to consider the case, i.e., \([\lambda_{r+1}]_i = (1 - \tau)[\lambda_r]_i + \beta_r g_i(x_{r+1}), i \in A_{r+1} \cap S_r\). Here, \(i\) denotes the index of these active constraints. Therefore, we only need to consider active constraints at \(x_{r+1}\) and corresponding \(\lambda_{r+1}^g\) and \(\lambda_{r+1}^\prime\), where notation \(\lambda_{r+1}^g\) means that the \(i\)th entry of \(\lambda_{r+1}\) is

\[
[\lambda_{r+1}^g]_i = \begin{cases} 
[\lambda_r]_i, & \text{if } i \in A_{r+1} \cap S_r; \\
0, & \text{otherwise.}
\end{cases} \tag{123}
\]

Let \(\tilde{\lambda}_{r+1}^g\) be a vector whose \(i\)th entry is

\[
[\tilde{\lambda}_{r+1}^g]_i = \begin{cases} 
[\lambda_{r+1}]_i, & \text{if } i \in A_{r+1}; \\
0, & \text{otherwise.}
\end{cases} \tag{124}
\]

and

\[
[\tilde{\lambda}_{r+1}']_i = \begin{cases} 
[\lambda_r]_i, & \text{if } i \in A_{r+1}; \\
0, & \text{otherwise.}
\end{cases} \tag{125}
\]

By defining the following auxiliary variable

\[
\tilde{\lambda}_{r+1}^g \triangleq (1 - \tau)(x_{r+1})\lambda_r + \beta_r(x_{r+1})g_r(x_{r+1}),
\]

we have

\[
\begin{aligned}
\text{dist} \left( J^T(x_{r+1})\tilde{\lambda}_{r+1}^g, -N_X(x_{r+1}) \right) \\
= \text{dist} \left( \beta_r J^T(x_{r+1})g_r(x_{r+1}) + (1 - \tau)J^T(x_{r+1})\tilde{\lambda}_{r+1}^g, -N_X(x_{r+1}) \right) \\
&\geq \beta_r \text{dist} (J^T(x_{r+1})g_r(x_{r+1}), -N_X(x_{r+1})) - \text{dist} \left( (1 - \tau)J^T(x_{r+1})\tilde{\lambda}_{r+1}^g, -N_X(x_{r+1}) \right) \\
&\geq \beta_r \sigma \|g_r(x_{r+1})\| - (1 - \tau)U_J \|\lambda_r\| \tag{126}
\end{aligned}
\]

where in (a) we use the inverse triangle inequality, in (b) we use the triangle inequality and convexity of feasible set \(X\), and in (c) we apply the regularity condition (14).

Based on (124), (125), we have

\[
\|\lambda_{r+1}^g\| \leq \|\tilde{\lambda}_{r+1}^g\| \leq (1 - \tau)\|\tilde{\lambda}_{r+1}^g\| + \beta_r \|g_r(x_{r+1})\| \leq (1 - \tau)\|\lambda_r\| + \beta_r \|g_r(x_{r+1})\|. \tag{131}
\]

Combining (130) and (131), it is sufficient to show \(\frac{\sigma}{2} \|\lambda_{r+1}^g\| \leq \text{dist}(J^T(x_{r+1})\tilde{\lambda}_{r+1}^g, -N_X(x_{r+1}))\) if

\[
\frac{\sigma}{2} ((1 - \tau)\|\lambda_r\| + \beta_r \|g_r(x_{r+1})\|) \leq \sigma \beta_r \|g_r(x_{r+1})\| - (1 - \tau)U_J \|\lambda_r\|,
\]

which requires

\[
\beta_r \geq \frac{2(1 - \tau)(\frac{\sigma}{2} + U_J)\|\lambda_r\|}{\sigma}. \tag{132}
\]

According to the upper bound of \(\lambda\) given in (112), we have when
then,
\[
\frac{\sigma}{2} \| \lambda_{r+1}^g \| \leq \text{dist} \left( J^T(x_{r+1}) \tilde{\lambda}_{r+1}^g, -N_{\mathcal{X}}(x_{r+1}) \right).
\]

Next, we need further to deal with the case where \( i \in A_{r+1} \cap \mathcal{S}_r \) in the sense that \( g_i(x_r) \geq 0 \) but \( g_i(x_{r+1}) > 0 \), i.e.,

\[
\text{dist} \left( J^T(x_{r+1}) \tilde{\lambda}_{r+1}^g, -N_{\mathcal{X}}(x_{r+1}) \right)
\]

\[ \leq (1 - \tau)U_{J} \| \tilde{\lambda}_{r+1}^g \| + U_{J} \beta_r \| \tilde{g}(x_{r+1}) \| + \text{dist} \left( J^T(x_{r+1}) \lambda_{r+1}^g, -N_{\mathcal{X}}(x_{r+1}) \right) \]

\[ \leq (1 - \tau)U_{J} \| \tilde{\lambda}_{r+1}^g \| + U_{J} \beta_r L_g \| x_{r+1} - x_r \| + \text{dist} \left( J^T(x_{r+1}) \lambda_{r+1}^g, -N_{\mathcal{X}}(x_{r+1}) \right)
\]

where in (a) we use the triangle inequality and the following definition of \( \tilde{\lambda}_{r+1}^g \), i.e.,

\[
[\tilde{\lambda}_{r+1}^g]_i = \begin{cases} [\lambda_{r+1}]_i, & \text{if } i \in A_{r+1} \cap \mathcal{S}_r; \\ 0, & \text{otherwise}. \end{cases}
\]

in (b) we define

\[
[\tilde{\lambda}_{r+1}^g]_i = \begin{cases} [\lambda_r]_i, & \text{if } i \in A_{r+1} \cap \mathcal{S}_r; \\ 0, & \text{otherwise}. \end{cases}
\]

\[
\tilde{g}(x_{r+1}) = \begin{cases} g_i(x_{r+1}), & \text{if } i \in A_{r+1} \cap \mathcal{S}_r; \\ 0, & \text{otherwise}. \end{cases}
\]

and use

\[
[\tilde{\lambda}_{r+1}^g]_i = (1 - \tau)[\tilde{\lambda}_{r}^g]_i + \beta_r \tilde{g}(x_{r+1}), \quad i \in A_{r+1} \cap \mathcal{S}_r,
\]

and (c) is true because we define

\[
\tilde{g}'(x_r) = \begin{cases} g_i(x_r) \leq 0, & \text{if } i \in A_{r+1} \cap \mathcal{S}_r; \\ 0, & \text{otherwise}. \end{cases}
\]

and apply

\[
\| \tilde{g}(x_{r+1}) + \tilde{g}'(x_r) \| \leq L_g \| x_{r+1} - x_r \|.
\]

Given condition (138), we will show the recursion of \( \lambda_r^g \) as follows.

From (10), we have

\[
\text{dist} \left( \nabla f(x_r) + J^T(x_r)(1 - \tau)\lambda_r + \beta_r g(x_r) \right)_{+} + \frac{1}{\alpha_r} (x_{r+1} - x_r), -N_{\mathcal{X}}(x_{r+1}) = 0,
\]
then we re-order some terms and get
\[
\begin{align*}
\nabla f(x_r) + J^T(x_r)[(1 - \tau)\lambda_r + \beta_r g(x_r)]_+ + \frac{1}{\alpha_r}(x_{r+1} - x_r) \\
= \nabla f(x_r) + J^T(x_r)[(1 - \tau)\lambda_r + \beta_r g(x_r)]_+ + J^T(x_{r+1})\lambda_{r+1}^g - J^T(x_{r+1})\lambda_r^g \\
+ J^T(x_r)\lambda_{r+1} - J^T(x_r)\lambda_{r+1} + \frac{1}{\alpha_r}(x_{r+1} - x_r)
\end{align*}
\]
(146)

where in (a) we add and subtract some same terms.

For convenience of equation expression, we define
\[
\nabla f(x_r) + J^T(x_r)[(1 - \tau)\lambda_r + \beta_r g(x_r)]_+ - J^T(x_r)\lambda_{r+1}
\]
(147)

\[
\begin{align*}
+ J^T(x_r)\lambda_{r+1} - J^T(x_{r+1})\lambda_r^g + J^T(x_{r+1})\lambda_r^g - J^T(x_{r+1})\lambda_r^g + \frac{1}{\alpha_r}(x_{r+1} - x_r)
\end{align*}
\]

Using the inverse triangle inequality, we have
\[
\begin{align*}
0 = \text{dist}(J^T(x_{r+1})\lambda_{r+1}^g + b, -N_X(x_{r+1})) \\
= \text{dist}(J^T(x_{r+1})\lambda_{r+1}^g, -N_X(x_{r+1})) - \|b\|. \\
\end{align*}
\]
(149)

So, we can write (145) as
\[
\text{dist}(J^T(x_{r+1})\lambda_{r+1}^g + b, -N_X(x_{r+1})) = 0.
\]

Using the inverse triangle inequality, we have
\[
\begin{align*}
0 = \text{dist}(J^T(x_{r+1})\lambda_{r+1}^g + b, -N_X(x_{r+1})) \\
= \text{dist}(J^T(x_{r+1})\lambda_{r+1}^g, -N_X(x_{r+1})) - \|b\|. \\
\end{align*}
\]
(150)

Applying the regularity condition (138), we have
\[
\begin{align*}
\frac{\sigma}{2}\|\lambda_{r+1}^g\| \leq \text{dist}(J^T(x_{r+1})\lambda_{r+1}^g, -N_X(x_{r+1})) \\
\leq \|b\| + (1 - \tau)U_J\|\lambda_{r+1}^g\| + U_J\beta_r L_g\|x_{r+1} - x_r\|. \\
\end{align*}
\]
(151)

Substituting (148) into \(\|b\|\), we have
\[
\begin{align*}
\|b\| \leq \|\nabla f(x_r)\| + \frac{1}{\alpha_r}\|x_{r+1} - x_r\| + (1 - \tau)U_J\|\lambda_{r+1} - \lambda_r\| + L_J\|\lambda_r\||x_{r+1} - x_r| \\
+ U_J\beta_r L_g\|x_{r+1} - x_r\| + \frac{1}{\alpha_r}\|x_{r+1} - x_r\|
\end{align*}
\]
(152)

where in (a) we use Assumption 4, i.e., \(\|\nabla f(x)\| \leq M, \forall x\), and use the following facts to bound the other terms in (148):

1. apply gradient Lipschitz continuity so that we have
\[
\begin{align*}
\|[1 - \tau]\lambda_r + \beta_r g(x_r)]_+ - \lambda_{r+1}\|
= \nabla \lambda_r \leq \lambda_r \\
(154)
\end{align*}
\]

where (a) is true because of the definition of \(\lambda_{r+1}^g\) introduced in (11) and (13b), in (b) we use non-expansiveness of the projection operator and the triangle inequality;

2. use the boundedness of the Jacobian matrix so we can get
\[
\|J^T(x_{r+1})\lambda_r^g - J^T(x_{r+1})\lambda_{r+1}^g\| \leq U_J\|\lambda_{r+1} - \lambda_r\|;
\]
(155)
iii) we re-organize terms as follows

\[ J^T(x_r)\lambda_{r+1} - J^T(x_{r+1})\lambda_{r+1}' = J^T(x_r)\lambda_{r+1} - J^T(x_r)\lambda_{r+1}' + J^T(x_r)\lambda_{r+1} - J^T(x_{r+1})\lambda_{r+1}' = J^T(x_r)\lambda_{r+1} - J^T(x_r)\lambda_{r+1}' + J^T(x_r)\lambda_{r+1} - J^T(x_{r+1})\lambda_{r+1}' - J^T(x_{r+1})\lambda_{r+1}' \]

which can give us the following inequalities directly

\[ \|J^T(x_r)\lambda_{r+1} - J^T(x_{r+1})\lambda_{r+1}'\| \]

\[ \leq \|J^T(x_r)\lambda_{r+1} - J^T(x_r)\lambda_{r+1}'\| + U_j\|\lambda_{r+1} - \lambda_r\| + L_j\|\lambda_r\||x_{r+1} - x_r| \]

\[ \leq (1 - \tau)U_j\|\lambda_r\| + U_j\|\lambda_{r+1} - \lambda_r\| + L_j\|\lambda_r\||x_{r+1} - x_r| \]

where (a.1) is true because based on the definition of \(\lambda_{r+1}'\), and we also use the upper bound of \(\|J^T(x_r)\lambda_{r+1} - J^T(x_r)\lambda_{r+1}'\|\), which is obtained by the following steps:

\[ \|J^T(x_r)\lambda_{r+1} - J^T(x_r)\lambda_{r+1}'\| \]

\[ \leq (1 - \tau)U_j\|\lambda_r\| \]

where (a.2) is true due to \(\lambda_{r+1}' = 0\), the notation \(g'\) follows (26), i.e., the i-th entry of \(g'(x_{r+1})\) is

\[ [g'(x_{r+1})]_i = \begin{cases} g_i(x_{r+1}), & \text{if } i \in A_{r+1} \cap S_r; \\ 0, & \text{otherwise}. \end{cases} \]

and (a.3) is true since we use the following facts

1. When \(i \in A_{r+1} \cap S_r\), then \([1 - \tau][\lambda_r']_i + \beta_r g_i(x_{r+1})]_+ - [(1 - \tau)\lambda_{r+1}'_i + \beta_r g_i(x_{r+1})]_+ = 0.\)

2. When \(i \in \bar{A}_{r+1} \cap S_r\), i.e., \([g(x_{r+1})]_i \leq 0\) and \((1 - \tau)[\lambda_r]_i + \beta_r g_i(x_r) \geq 0\), then we have

\[ \left[\left[(1 - \tau)[\lambda_r']_i + \beta_r g_i(x_{r+1})]_+ - [(1 - \tau)\lambda_{r+1}'_i + \beta_r g_i(x_{r+1})]_+\right]\right] = \left[\left[(1 - \tau)[\lambda_r']_i + \beta_r g_i(x_{r+1})]_+\right]\right], \forall i \in \bar{A}_{r+1} \cap S_r. \]

In summary, we have (160).

Substituting (153) into (151), we know that

\[ \frac{\sigma}{2}\|\lambda_{r+1}'\| \leq M + \left(\frac{1}{\alpha_r} + 2U_j\beta_r L_g + L_j\|\lambda_r\|\right)\|x_{r+1} - x_r\| + 2U_j\|\lambda_{r+1} - \lambda_r\| + 2(1 - \tau)U_j\|\lambda_r\|. \]

Combining the regularity condition (138), we have that

\[ \frac{\sigma^2}{4}\|\lambda_{r+1}'\|^2 \leq 4M^2 + 4\left(\frac{1}{\alpha_r} + 2U_j\beta_r L_g + L_j\|\lambda_r\|\right)^2\|x_{r+1} - x_r\|^2 + 16U_j^2\|\lambda_{r+1} - \lambda_r\|^2 + 16(1 - \tau)^2U_j^2\|\lambda_r\|^2. \]

Note that

\[ \frac{1}{\alpha_r} + 2U_j\beta_r L_g + L_j\|\lambda_r\| = \frac{1 + 2U_jL_g\beta_r \alpha_r + \alpha_r L_j\|\lambda_r\|}{\alpha_r} \leq \frac{3}{\alpha_r}. \]

Therefore, we have

\[ \sigma^2\|\lambda_{r+1}'\|^2 \leq 16M^2 + \frac{36}{\alpha_r}\|x_{r+1} - x_r\|^2 + 64U_j^2\|\lambda_{r+1} - \lambda_r\|^2 + 64(1 - \tau)^2U_j^2\|\lambda_r\|^2. \]

The proof is complete. \(\Box\)
C.4. Upper bound of Sum of Dual Variables: proof of Lemma 4

Proof. We will use mathematical induction to obtain the upper bound of \( \sum_{r=1}^{T} \alpha_r^2 \| \mathbf{x}_r \|^2 \).

It is trivial to show the case when \( T = 1 \). Then, we assume that

\[
\sum_{r=1}^{R} \alpha_r^2 \| \mathbf{x}_r \|^2 \sim O(\beta_R), \forall R \leq T,
\]

(167)

i.e., there exists a constant \( \Lambda \) such that

\[
\sum_{r=1}^{R} \alpha_r^2 \| \mathbf{x}_r \|^2 \leq \Lambda \beta_R, \forall R.
\]

(168)

In the following, we will show that

\[
\sum_{r=1}^{R} \alpha_r^2 \| \mathbf{x}_{r+1} \|^2 \leq \Lambda \beta_R \leq \Lambda \beta_{R+1}, \forall R.
\]

(169)

**Step 1: Upper bound of the size of the difference of two successive primal and dual variables**

Using (89) as shown in Lemma 7, we have

\[
\frac{1}{2\beta_r} \| \mathbf{x}_{r+1} - \mathbf{x}_r \|^2 + \frac{1}{4\alpha_r} \| \mathbf{x}_{r+1} - \mathbf{x}_r \|^2
\]

\[
\leq \frac{1}{2\beta_r} \| \mathbf{x}_{r+1} - \mathbf{x}_r \|^2 + \frac{2\theta}{\beta_r} \left( \frac{\gamma_{r-2} - \gamma_{r-1}}{\gamma_r} \right) \| \mathbf{x}_r \|^2 + \frac{2\theta}{\tau} \left( \frac{1}{\beta_{r-1}} - \frac{1}{\beta_r} \right) (\| \mathbf{x}_r - \mathbf{x}_{r-1} \|^2 + \| \mathbf{x}_{r+1} - \mathbf{x}_r \|^2)
\]

\[
+ \left( \frac{1}{2} + \frac{2\theta}{\tau} \right) \left( \frac{1}{\beta_r} - \frac{1}{\beta_{r-1}} \right) \| \mathbf{x}_r - \mathbf{x}_{r-1} \|^2 + \frac{2\theta}{\beta_r} \left( \frac{2}{\beta_{r-1}} - \frac{2}{\beta_r} \right) \left( \frac{\gamma_{r-2}}{\gamma_{r-1}} - 1 \right) \| \mathbf{x}_r \|^2
\]

\[
+ (\beta_{r+1} - \beta_r) \| g_1(\mathbf{x}_{r+1}) \|^2 + \left( \frac{1}{\beta_r} - \frac{1}{\beta_{r+1}} \right) (1 - \tau)^2 \| \mathbf{x}_{r+1} \|^2 + \left( \frac{\gamma_{r-1} - \gamma_r}{2} \right) \| \mathbf{x}_{r+1} \|^2
\]

(170)

\[
\leq \frac{1}{2\beta_r} \| \mathbf{x}_{r+1} - \mathbf{x}_r \|^2 + \frac{2\theta}{\beta_r} \left( \frac{\gamma_{r-2} - \gamma_{r-1}}{\gamma_r} \right) \| \mathbf{x}_r \|^2 + \frac{2\theta}{\tau} \left( \frac{1}{\beta_{r-1}} - \frac{1}{\beta_r} \right) \| \mathbf{x}_{r+1} - \mathbf{x}_r \|^2
\]

\[
+ \theta \left( \frac{2}{\beta_{r-1}} - \frac{2}{\beta_r} \right) \left( \frac{\gamma_{r-2}}{\gamma_{r-1}} - 1 \right) \| \mathbf{x}_r \|^2 + (\beta_{r+1} - \beta_r) \| g_1(\mathbf{x}_{r+1}) \|^2
\]

\[
+ \left( \frac{1}{\beta_r} - \frac{1}{\beta_{r+1}} \right) \| \mathbf{x}_{r+1} \|^2 + \left( \frac{2\gamma_{r-1} - \gamma_r}{2} \right) \| \mathbf{x}_{r+1} \|^2
\]

(171)

where in (a) we apply Young’s inequality, and (b) is true because \( \beta_r \) is increasing, so the coefficient in front of term \( \| \mathbf{x}_r - \mathbf{x}_{r-1} \|^2 \) is

\[
\frac{2}{\tau} \left( \frac{1}{\beta_{r-1}} - \frac{1}{\beta_r} \right) + \left( \frac{1}{2} + \frac{2}{\tau} \right) \left( \frac{1}{\beta_r} - \frac{1}{\beta_{r-1}} \right) = \frac{1}{2} \left( \frac{1}{\beta_r} - \frac{1}{\beta_{r-1}} \right) < 0.
\]

(172)
Multiplying 4 on both sides of (171), we can further have

\[
\frac{2}{\beta_r} \|\lambda_{r+1} - \lambda_r\|^2 + \frac{1}{\alpha_r} \|x_{r+1} - x_r\|^2 \\
\leq 4 \left( P_r - P_{r+1} + \frac{2\theta}{\beta_r} \left( \frac{\gamma_{r-2}}{\gamma_{r-1}} - \frac{\gamma_{r-1}}{\gamma_{r}} \right) \|\lambda_r\|^2 + \frac{2\theta}{\tau} \left( \frac{1}{\beta_{r-1}} - \frac{1}{\beta_r} \right) \|\lambda_{r+1} - \lambda_r\|^2 \\
+ \theta \left( \frac{2}{\beta_{r-1}} - \frac{2}{\beta_r} \right) \left( \frac{\gamma_{r-2}}{\gamma_{r-1}} - 1 \right) \|\lambda_r\|^2 + (\beta_{r+1} - \beta_r) \|g_1(x_{r+1})\|^2 \\
+ \left( \frac{1}{\beta_r} - \frac{1}{\beta_{r+1}} \right) \|\lambda_{r+1}\|^2 + \left( \frac{\gamma_{r-1} - \gamma_r}{2} \right) \|\lambda_{r+1}\|^2 \right)
\]

(173)

\[
\leq 4(P_r - P_{r+1}) + \frac{8\theta}{\tau} \left( \frac{1}{\beta_{r-1}} - \frac{1}{\beta_r} \right) \|\lambda_{r+1} - \lambda_r\|^2 + 4 \left( \left( \frac{1}{\beta_r} - \frac{1}{\beta_{r+1}} \right) + \frac{1}{2} \frac{\gamma_{r-1} - \gamma_r}{2} \right) \|\lambda_{r+1}\|^2 \\
+ \frac{8\theta}{\gamma_{r-1}\beta_{r-1}} \|\lambda_r\|^2 + 4(\beta_{r+1} - \beta_r) \|g_1(x_{r+1})\|^2
\]

(174)

\[
\leq 4(P_r - P_{r+1}) + \frac{8\theta}{\tau} \left( \frac{1}{\beta_{r-1}} - \frac{1}{\beta_r} \right) \|\lambda_{r+1} - \lambda_r\|^2 + 4 \left( \left( \frac{1}{\beta_r} - \frac{1}{\beta_{r+1}} \right) + \frac{1}{2} \frac{\gamma_{r-1} - \gamma_r}{2} \right) \|\lambda_{r+1}\|^2 \\
+ \frac{8\theta}{\gamma_{r-1}\beta_{r-1}} \|\lambda_r\|^2 + 4(\beta_{r+1} - \beta_r) \|g_1(x_{r+1})\|^2
\]

(175)

\[
\leq 4(P_r - P_{r+1}) + \left( \frac{8\theta}{\tau} \left( \frac{1}{\beta_{r-1}} - \frac{1}{\beta_r} \right) + 4 \left( \frac{1}{\beta_r} - \frac{1}{\beta_{r+1}} \right) \right) \|\lambda_{r+1} - \lambda_r\|^2 \\
+ 4 \left( \left( \frac{1}{\beta_r} - \frac{1}{\beta_{r+1}} \right) + \frac{1}{2} \frac{\gamma_{r-1} - \gamma_r}{2} \right) \|\lambda_{r+1}\|^2 \\
+ \left( \frac{8\theta}{\gamma_{r-1}\beta_{r-1}} \right) \|\lambda_r\|^2 + 4(\beta_{r+1} - \beta_r) \|g_1(x_{r+1})\|^2
\]

(176)

where in (a) as \(\gamma_r\) is a decreasing sequence we have

\[
\left( \frac{\gamma_{r-2} - \gamma_{r-1}}{\gamma_{r-1} - \gamma_{r}} \right) \leq \frac{\gamma_{r-2}}{\gamma_{r-1} - \gamma_{r}} - 1 \leq \frac{\gamma_{r-2} - \gamma_{r-1}}{\gamma_{r-1} - \gamma_{r}} ,
\]

(177)

and we also use \(\beta_r\) is a increasing sequence, (b) is true due to \(0 < \gamma_r \beta_r = \tau < 1, \forall r\), and in (c) from (29) and (13b), we know that

\[
\|g_1(x_{r+1})\|^2 \leq \frac{2}{\beta_r} \left( \|\lambda_{r+1} - \lambda_r\|^2 + \tau^2 \|\lambda_r\|^2 \right)
\]

(178)

so, we have

\[
(\beta_{r+1} - \beta_r) \|g_1(x_{r+1})\|^2 \leq \frac{2(\beta_{r+1} - \beta_r)}{\beta_r^2} \left( \|\lambda_{r+1} - \lambda_r\|^2 + \tau^2 \|\lambda_r\|^2 \right)
\]

(179)

\[
\leq 2 \left( \frac{1}{\beta_r} - \frac{1}{\beta_{r+1}} \right) \beta_{r+1} \left( \|\lambda_{r+1} - \lambda_r\|^2 + \tau^2 \|\lambda_r\|^2 \right)
\]

(180)

\[
\leq 4 \left( \frac{1}{\beta_r} - \frac{1}{\beta_{r+1}} \right) \left( \|\lambda_{r+1} - \lambda_r\|^2 + \tau^2 \|\lambda_r\|^2 \right)
\]

(181)

where the last inequality is true because \(\beta_r\) is an increasing sequence and chosen as \(O(r^{1/3})\), e.g., \(\beta_r = \beta_0 r^{1/3}\).

Note that we choose stepsizes \(\beta_r\) as (17), then

\[
\frac{1}{\beta_r} - \frac{1}{\beta_{r+1}} \sim \gamma_r - \gamma_{r+1} \sim \alpha_r - \alpha_{r+1}
\]

(182)

\[
\frac{1}{r^{1/3}} - \frac{1}{(r+1)^{1/3}} \leq \frac{(r+1)^{1/3} - r^{1/3}}{r^{2/3}} \leq \frac{1}{3r^{4/3}} \sim O \left( \frac{1}{r^{4/3}} \right) \sim \alpha_r \sim \gamma_r \sim \frac{1}{\beta_r^4}
\]

(183)
where in (a) we use the gradient Lipschitz continuity of function $x^{1/3}$, i.e., $(x + y)^{1/3} - x^{1/3} = y / (3x^{2/3})$ for any $x, y \geq 1$.

Given these results, we can have if $\beta_r = \beta_0 r^{1/3}$, then $1 / \beta_r - 1 / \beta_{r+1} \leq \frac{1}{\beta_0 r^{2/3}}$ and $1 / \beta_{r-1} - 1 / \beta_r \leq \frac{1}{\beta_0 r^{2/3}(r-1)} \leq \frac{\beta_0}{\beta_0 r^{2/3}}$. It is easy to check that when $r \geq 3$, then $4(1 / \beta_r - 1 / \beta_{r+1}) < 1/(2\beta_r)$ and when $r > (16\theta)/(3\gamma) + 1$, then $(8\theta)/\tau(1/\beta_{r-1} - 1/\beta_r) < 1/(2\beta_r) \gamma$. Therefore, (176) can be simplified as

$$\frac{1}{\beta_r} \| \lambda_{r+1} - \lambda_r \|^2 + \frac{1}{\alpha_r} \| x_{r+1} - x_r \|^2 \leq 4(P_r - P_{r+1}) + 4 \left( \frac{1}{\beta_r} - \frac{1}{\beta_{r+1}} + \tau \left( \frac{1}{\beta_r} - \frac{1}{\beta_{r+1}} \right) \right) \| \lambda_{r+1} \|^2 + \left( 8\theta - \frac{3\gamma}{\beta_0 r^{2/3}} + 4 \right) \| \lambda_r \|^2 (184)$$

and

$$4(P_r - P_{r+1}) + 4 \left( \frac{1}{\beta_0 r^{4/3}} + \frac{3/2}{\beta_0 r^{4/3}} \right) \| \lambda_{r+1} \|^2 + \left( 8\theta - \frac{3\gamma}{\beta_0 r^{4/3}} + 4 \right) \| \lambda_r \|^2 (185)$$

where in (a) we use (183) again and $r \geq 3$, and (b) is true by a direct numerical calculation.

**Step 2: Recursion of upper bound of dual variable**

Multiplying $\alpha_r$ on both sides of (25) shown in Lemma 3, we have

$$\alpha_r \sigma^2 \| \lambda_{r+1} \|^2 \leq 16 \alpha_r M^2 + \frac{36}{\alpha_r} \| x_{r+1} - x_r \|^2 + \alpha_r 64U^2 \| \lambda_{r+1} - \lambda_r \|^2 + 64 \alpha_r (1 - \gamma)^2 U^2 \| \lambda_r \|^2 (187)$$

$$\leq 16 \alpha_r M^2 + \max \left\{ 36, \frac{64U^2}{L_g} \right\} \left( \frac{1}{\alpha_r} \| x_{r+1} - x_r \|^2 + \frac{1}{\beta_r} \| \lambda_{r+1} - \lambda_r \|^2 \right) + 64 \alpha_r (1 - \gamma)^2 U^2 \| \lambda_r \|^2 (188)$$

Then, substituting (186) into (188) gives

$$\alpha_r (r+1)^2 \| \lambda_{r+1} \|^2 \leq \alpha_r \sigma^2 \| \lambda_{r+1} \|^2 \leq 16 \alpha_r M^2 + \max \left\{ 36, \frac{64U^2}{L_g} \right\} \left( 4(P_r - P_{r+1}) + \frac{2.5}{\beta_0 r^{4/3}} \| \lambda_{r+1} \|^2 + \frac{13\theta}{\beta_0 r^{4/3}} \| \lambda_r \|^2 \right) + 64 \alpha_r (1 - \gamma)^2 U^2 \| \lambda_r \|^2 (189)$$

where we use the fact that $\alpha_r$ is decreasing.

We further multiply another $\alpha_r$ on both sides of (189) and can get

$$\alpha_r \sigma^2 \| \lambda_{r+1} \|^2 \leq 16 \alpha_r M^2 + 64 (1 - \gamma)^2 U^2 \alpha_r \| \lambda_r \|^2 + \alpha_r \max \left\{ 36, \frac{64U^2}{L_g} \right\} \left( 4(P_r - P_{r+1}) + \frac{2.5}{\beta_0 r^{4/3}} \| \lambda_{r+1} \|^2 + \frac{13\theta}{\beta_0 r^{4/3}} \| \lambda_r \|^2 \right) (190)$$

where we use the fact that $\alpha_r$ is a decreasing sequence.

**Step 3: Telescoping sum of dual variables**

Recall the potential function: from (6) and (90), we know

$$\mathcal{P}_r = f(x_r) + \frac{\beta_r}{2} \left[ \left\| g(x_r) + \frac{(1 - \gamma) \lambda_r}{\beta_r} \right\| \right]^2 - \frac{\| (1 - \gamma) \lambda_r \|^2}{2\beta_r} + (1 - \gamma) \left( \frac{1}{2\beta_r} - \frac{2\theta}{\beta_r} \right) \| \lambda_r - \lambda_{r-1} \|^2 - \frac{(1 - \gamma) \gamma_{r+1}}{2} \| \lambda_r \|^2 - \frac{2\theta}{\beta_r} \left( \frac{\gamma_{r+1}}{\gamma_{r-1}} - 1 \right) \| \lambda_r \|^2. (191)$$

Note that running a constant number of iterations as a warm start for an algorithm will not affect the iteration complexity. So, this condition can be easily satisfied without hurting the final convergence rate guarantees.
Applying the telescoping sum of (190) over \( r = 1, \ldots, R \), we have from (191)

\[
\begin{align*}
\sigma^2 \sum_{r=1}^{R} \alpha_{r+1}^2 \|\lambda_{r+1}\|^2 \\
\leq 16M^2 \sum_{r=1}^{R} \alpha_r^2 \\
+ \max \left\{ 36, \frac{64U_J}{L_g} \right\} 4\alpha_1 \left( f(x_1) + \frac{\beta_1}{2} \left\| g(x_1) + \frac{(1-\tau)\lambda_1}{\beta_1} \right\|^2 \right) + (1-\tau) \left( \frac{1}{2\beta_0} + \frac{2\vartheta}{\beta_0\tau} \right) \|\lambda_1 - \lambda_0\|^2 - f^*
\right) \\
+ \max \left\{ 36, \frac{64U_J}{L_g} \right\} \sum_{r=1}^{R} \frac{2.5}{\beta_0 r^{4/3}} \alpha_r \|\lambda_r\|^2 + \max \left\{ 36, \frac{64U_J}{L_g} \right\} \sum_{r=1}^{R} \frac{13\vartheta}{\beta_0 r^{4/3}} \alpha_r \|\lambda_r\|^2 \\
+ 64(1-\tau)^2U_J^2 \sum_{r=1}^{R} \alpha_r^2 \|\lambda_r\|^2 \\
(1) \leq 4M^2 \sum_{r=1}^{R} \alpha_r^2 + 4 \max \left\{ 36, \frac{64U_J}{L_g} \right\} \alpha_1 \Delta_F + 4 \max \left\{ 36, \frac{64U_J}{L_g} \right\} \alpha_1 \frac{4G (1 + \frac{1}{\vartheta}) \tau}{(1-\eta)\beta_0} \\
+ \max \left\{ 36, \frac{64U_J}{L_g} \right\} \sum_{r=1}^{R} \frac{2.5}{\beta_0 r^{4/3}} \alpha_r \|\lambda_r\|^2 + \max \left\{ 36, \frac{64U_J}{L_g} \right\} \sum_{r=1}^{R} \frac{13\vartheta}{\beta_0 r^{4/3}} \alpha_r \|\lambda_r\|^2 \\
+ 64(1-\tau)^2U_J^2 \sum_{r=1}^{R} \alpha_r^2 \|\lambda_r\|^2
\end{align*}
\]

where in (a) we use the fact that

\[
\frac{2}{\beta_r} \left( \frac{\gamma_{r-1}}{\gamma_r} - 1 \right) = \frac{2\gamma_r}{\tau} \left( \frac{\gamma_{r-1}}{\gamma_r} - 1 \right) = \frac{2}{\beta_{r-1}} \left( \frac{\gamma_{r-1}}{\gamma_r} - 1 \right) = \frac{2}{\beta_{r-1}} - \frac{2}{\beta_r}.
\]

so that we can have

\[
\begin{align*}
\frac{(1-\tau)^2}{\beta_{R+1}} \|\lambda_{R+1}\|^2 + \frac{(1-\tau)\gamma_R}{2} \|\lambda_{R+1}\|^2 + \frac{2\vartheta}{\beta_R} \left( \frac{\gamma_{R-1}}{\gamma_R} - 1 \right) \|\lambda_{R+1}\|^2 \\
\leq \frac{(1-\tau)^2}{\beta_{R+1}} \|\lambda_{R+1}\|^2 + \frac{(1-\tau)\tau}{2\beta_R} \|\lambda_{R+1}\|^2 + \left( \frac{2\vartheta}{\beta_{R-1}} - \frac{2\vartheta}{\beta_R} \right) \|\lambda_{R+1}\|^2 \\
\leq \frac{1-\frac{\tau}{2}}{\beta_{R+1}} \frac{\gamma_{R-1}}{\gamma_R} \|\lambda_{R+1}\|^2 + \frac{2\vartheta}{\beta_{R-1}} \|\lambda_{R+1}\|^2 \\
\leq \frac{2}{\beta_{R-1}} \|\lambda_{R+1}\|^2 \\
(1) \leq 2G (1 + \frac{1}{\vartheta}) \frac{R^2/3}{(1-\eta)\beta_{R-1}} \leq 4G (1 + \frac{1}{\vartheta}) \frac{R^{1/3}}{(1-\eta)\beta_0}.
\end{align*}
\]
Then, we can obtain

\[
\sigma^2 \sum_{r=1}^{R} \alpha_r^2 \| \lambda_{r+1} \|^2 \leq R^{1/3} \left( \frac{16 M^2}{\beta_0^2 U_L L_g} + 4 \max \left\{ 36, \frac{64 U_J}{L_g} \right\} \alpha_1 \frac{4 G \left( 1 + \frac{1}{\tau} \right)}{(1 - \eta) \beta_0} \right) + 4 \max \left\{ 36, \frac{64 U_J}{L_g} \right\} \alpha_1 \Delta_F \\
+ \max \left\{ 36, \frac{64 U_J}{L_g} \right\} \sum_{r=1}^{R} \frac{2.5}{\beta_0^{4/3}} \alpha_r \| \lambda_{r+1} \|^2 + \max \left\{ 36, \frac{64 U_J}{L_g} \right\} \sum_{r=1}^{R} \frac{13 \theta}{\beta_0^{4/3}} \alpha_r \| \lambda_r \|^2 \\
+ 64 (1 - \tau)^2 U_J^2 \sum_{r=1}^{R} \alpha_r^2 \| \lambda_r \|^2
\]

(199)

where in (a) we use (193) and

\[
16 M^2 \sum_{r=1}^{R} \alpha_r^2 \leq 16 M^2 \sum_{r=1}^{R} \frac{1}{\beta_0^2 U_J L_g} \leq \frac{16 M^2 R^{1/3}}{\beta_0^2 U_J L_g},
\]

(202)

(b) follows as

\[
\alpha_r = \frac{\alpha_r}{\alpha_{r+1}} \leq \frac{(r + 1)^{1/3}}{r^{1/3}} \leq 2^{1/3} \alpha_{r+1} < 2 \alpha_{r+1}, \forall r \geq 1,
\]

(203)

and (c) is true when

\[
\alpha_r \geq \max \left\{ 36, \frac{64 U_J}{L_g} \right\} \frac{13 \theta}{(1 - \tau)^2 U_J^2 \beta_0^{4/3}}, \theta \geq 1
\]

(204)

i.e.,

\[
\alpha_r \geq \max \left\{ 36, \frac{64 U_J}{L_g} \right\} \frac{13 \theta}{(1 - \tau)^2 U_J^2 \beta_0 (r - 1)^{4/3}}, \forall r \geq 2,
\]

(205)

then, we can have

\[
\max \left\{ 36, \frac{64 U_J}{L_g} \right\} \frac{\max \{13 \theta, 5\}}{\beta_0^{4/3}} \leq (1 - \tau)^2 U_J^2 \alpha_r.
\]

(206)

For the case when \( g_i(x_{r+1}) \) \leq 0, we have \( \lambda_{r+1} \|^2 \leq (1 - \tau) \| \lambda_r \|^2 \). So, we have \( \alpha_{r+1}^2 | \lambda_{r+1}^2 \| \leq (1 - \tau)^2 \alpha_r^2 | \lambda_r^2 \|, \) i.e.,

\[
\sigma^2 \alpha_{r+1}^2 | \lambda_{r+1}^2 \|^2 \leq \sigma^2 (1 - \tau)^2 \alpha_r^2 | \lambda_r^2 \|^2, \text{ if } g_i(x_{r+1}) \leq 0.
\]

(207)
Then, from (201), we have
\[
\sigma^2 \sum_{r=1}^{R} \alpha_{r+1}^2 \| \lambda_{r+1} \|^2 \leq R^{1/3} \left( \frac{16M^2}{\beta_0^2 U_f L_g} + 4 \max \left\{ \frac{64U_f}{L_g} \right\} \alpha_0 \frac{4G (1 + \frac{1}{\rho})}{(1 - \eta)\beta_0} \right) + 4 \max \left\{ \frac{64U_f}{L_g} \right\} \alpha_1 \Delta_F \\
+ (66U_f^2 + \sigma^2)(1 - \tau)^2 \sum_{r=1}^{R} \alpha_r^2 \| \lambda_r \|^2 + \max \left\{ \frac{64U_f}{L_g} \right\} \frac{5}{\beta_0 R^{4/3}} \alpha R \| \lambda_{R+1} \|^2.
\]
(208)

Dividing \( \sigma^2 \) on both sides of (208) results in the following recursion
\[
\sum_{r=1}^{R} \alpha_{r+1}^2 \| \lambda_{r+1} \|^2 \leq \frac{R^{1/3}}{\sigma^2} \left( \frac{16M^2}{\beta_0^2 U_f L_g} + 4 \max \left\{ \frac{64U_f}{L_g} \right\} \alpha_0 \frac{4G (1 + \frac{1}{\rho})}{(1 - \eta)\beta_0} \right) + 4 \max \left\{ \frac{64U_f}{L_g} \right\} \alpha_1 \Delta_F \\
+ \frac{5}{\sigma^2} \max \left\{ \frac{64U_f}{L_g} \right\} \frac{\alpha_0 G (1 + \frac{1}{\rho})}{\beta_0 R} 1 - \eta + \frac{66U_f^2 + \sigma^2}{\sigma^2} \sum_{r=1}^{R} \alpha_r^2 \| \lambda_r \|^2.
\]
(209)

which follows from (112).

Then, when
\[
\frac{(66U_f^2 + \sigma^2)(1 - \tau)^2}{\sigma^2} \leq \rho < 1,
\]
(210)
i.e.,
\[
\tau > 1 - \frac{\sigma}{\sqrt{66U_f^2 + \sigma^2}}.
\]
(211)
then, we have
\[
\sum_{r=1}^{R} \alpha_{r+1}^2 \| \lambda_{r+1} \|^2 \leq \rho \Lambda \beta_0 R^{1/3} + \frac{4\alpha_1 \Delta_F}{\sigma^2} \max \left\{ \frac{64U_f}{L_g} \right\} + \frac{5}{\sigma^2} \max \left\{ \frac{64U_f}{L_g} \right\} \frac{\alpha_0 G (1 + \frac{1}{\rho})}{\beta_0 R} 1 - \eta \\
+ \frac{R^{1/3}}{\sigma^2} \left( \frac{16M^2}{\beta_0^2 U_f L_g} + 4 \alpha_1 \max \left\{ \frac{64U_f}{L_g} \right\} \frac{4G (1 + \frac{1}{\rho})}{(1 - \eta)\beta_0} \right).
\]

Therefore, when
\[
\Lambda \geq \frac{1}{\sigma^2(1 - \rho)\beta_0} \left( \frac{16M^2}{\beta_0^2 U_f L_g} + 4 \alpha_1 \max \left\{ \frac{64U_f}{L_g} \right\} \frac{4G (1 + \frac{1}{\rho})}{(1 - \eta)\beta_0} \right) + \frac{4\alpha_1 \Delta_F + 5 \frac{\alpha_0 G (1 + \frac{1}{\rho})}{\beta_0 R} 1 - \eta}{R^{1/3}\sigma^2(1 - \rho)\beta_0} \max \left\{ \frac{64U_f}{L_g} \right\},
\]
(212)
we can obtain
\[
\sum_{r=1}^{R} \alpha_{r+1}^2 \| \lambda_{r+1} \|^2 \leq \Lambda \beta_R,
\]
(213)
which completes the proof of showing (169).

\[\square\]

**D. Convergence Rate of GDPA to KKT Points**

*Proof. Stationarity.*

First, multiplying \( \beta_r \) on both sides of (176), we have
\[
\| \lambda_{r+1} - \lambda_r \|^2 + \frac{\beta_r}{\alpha_r} ||x_{r+1} - x_r||^2 \leq 4\beta_r (p_r - p_{r+1}) + \frac{2.5}{r} ||\lambda_{r+1}||^2 + \frac{13\theta}{r} ||\lambda_r||^2.
\]
(214)
From (41), we choose step-size $\alpha_r$ as $\alpha_{0,1}/(\alpha_{0,2} + \alpha_{0,3} r^{1/3})$. According to (112), we can see that if $\alpha_{0,3} \geq (1 - \tau) \sqrt{G(1 + \theta)} L_f + \beta_0 U J L_g$, then it is easy to obtain a constant as the lower bound of $\alpha_r\beta_r$, which satisfies (41). For example, when $\alpha_{0,2} \geq L_f$ and $\alpha_{0,1} < 1$, then $\alpha_r \geq 1/(\alpha_{0,2} + \alpha_{0,3} r^{1/3})$ and we can get

$$\alpha_r \beta_r = \frac{\alpha_{0,1} \beta_0 r^{1/3}}{\alpha_{0,2} + \alpha_{0,3} r^{1/3}} \geq \frac{\alpha_{0,1} \beta_0}{\alpha_{0,2} + \alpha_{0,3}} \triangleq I_1. \tag{215}$$

So, we can have equation (214) re-written as

$$\min \{1, I_1\} \left(\|\lambda_{r+1} - \lambda_r\|^2 + \frac{1}{\alpha_r^2} \|x_{r+1} - x_r\|^2\right) \leq \|\lambda_{r+1} - \lambda_r\|^2 + \frac{I_1}{\alpha_r^2} \|x_{r+1} - x_r\|^2$$

$$\leq 4\beta_r (P_r - P_{r+1}) + \frac{2.5}{r} \|\lambda_{r+1}\|^2 + \frac{13\theta}{r} \|\lambda_r\|^2. \tag{216}$$

From (23), we know

$$\|G(x_r, \lambda_r)|^2 \leq 4 \left(2 \left(\frac{3}{\alpha_r}\right)^2 + 2L_g^2 + 2U_J^2 L_g^2 \beta_r^2\right) \|x_{r+1} - x_r\|^2 + 4 \left(\frac{(3 + \tau)}{\beta_0}\right)^2 \|\lambda_{r+1} - \lambda_r\|^2 + 4\gamma_r^2 \|\lambda_{r+1}\|^2$$

$$\leq \frac{88}{\alpha_r^2} \|x_{r+1} - x_r\|^2 + 4 \left(\frac{16}{\beta_0^2} + 3\right) \|\lambda_{r+1} - \lambda_r\|^2 + 4\gamma_r^2 \|\lambda_{r+1}\|^2 \tag{217}$$

$$\leq \max \left\{88, 4 \left(\frac{16}{\beta_0^2} + 3\right)\right\} \left(\|\lambda_{r+1} - \lambda_r\|^2 + \frac{1}{\alpha_r^2} \|x_{r+1} - x_r\|^2\right) + 4\gamma_r^2 \|\lambda_{r+1}\|^2 \tag{218}$$

where (a) is true due to the increase of sequence $\beta_r$, and we require $\beta_0 \geq 1/U_J$. Combining (214) and (218), we know that there exists a constant $C$ such that

$$\|G(x_r, \lambda_r)|^2 \leq \max \left\{88, 4 \left(\frac{16}{\beta_0^2} + 3\right)\right\} \left(4\beta_r (P_r - P_{r+1}) + \frac{2.5}{r} \|\lambda_{r+1}\|^2 + \frac{13\theta}{r} \|\lambda_r\|^2\right) + 4\gamma_r^2 \|\lambda_{r+1}\|^2. \tag{219}$$
Applying the telescoping sum, we have that

\[
\sum_{r=1}^{T} \frac{1}{\beta_r} \|G(x_r, \lambda_r)\|^2 \leq 4C \left( \sum_{r=1}^{T} (P_r - P_{r+1}) + \sum_{r=1}^{T} \frac{2.5C}{r \beta_r} \|\lambda_{r+1}\|^2 + \sum_{r=1}^{T} \frac{13C \theta}{r \beta_r} \|\lambda_r\|^2 + 4 \sum_{r=1}^{T} \gamma_r^2 \|\lambda_{r+1}\|^2 \right)
\]

\[(191)(192)(196) \leq 4C \left( \Delta_F - (1 - \tau) \left( \frac{1}{2 \beta_T} + \frac{2 \theta}{\beta_T \tau} \right) \|\lambda_{T+1} - \lambda_T\|^2 + \left( 1 - \frac{3}{2} \tau + \frac{7}{2} \right) \frac{\beta_T}{\beta_T - 2} \right) \|\lambda_{T+1}\|^2 \]

\[+ \sum_{r=1}^{T} \frac{2.5C}{r \beta_r} \|\lambda_{r+1}\|^2 + \sum_{r=1}^{T} \frac{13C \theta}{r \beta_r} \|\lambda_r\|^2 + 4 \sum_{r=1}^{T} \gamma_r^2 \|\lambda_{r+1}\|^2 \]

\[(a) \leq 4C \left( \Delta_F - (1 - \tau) \left( \frac{1}{2 \beta_T} + \frac{2 \theta}{\beta_T \tau} \right) \|\lambda_{T+1} - \lambda_T\|^2 + \left( 1 - \frac{3}{2} \tau + \frac{7}{2} \right) \frac{\beta_T}{\beta_T - 2} \right) \|\lambda_{T+1}\|^2 \]

\[+ \sum_{r=1}^{T} \frac{2.5C}{r \beta_r} \|\lambda_{r+1}\|^2 + \sum_{r=1}^{T} \frac{13C \theta}{r \beta_r} \|\lambda_r\|^2 + 4 \sum_{r=1}^{T} \gamma_r^2 \|\lambda_{r+1}\|^2 \]

\[(b) \leq 4C \left( \Delta_F - (1 - \tau) \left( \frac{1}{2 \beta_T} + \frac{2 \theta}{\beta_T \tau} \right) \|\lambda_{T+1} - \lambda_T\|^2 + \left( 1 - \frac{3}{2} \tau + \frac{7}{2} \right) \frac{\beta_T}{\beta_T - 2} \right) \|\lambda_{T+1}\|^2 \]

\[+ \sum_{r=1}^{T} \frac{2.5C + 4 \gamma_r}{\beta_r^3} \|\lambda_r\|^2 + \sum_{r=1}^{T} \frac{13C \theta}{\beta_r^3} \|\lambda_r\|^2 + \frac{2.5C + 4 \gamma_r}{\beta_r^3} \|\lambda_{r+1}\|^2 \]

where in (a) we use (183) so that \(1/\beta_{T-1} - 1/\beta_T \leq 1/(T - 1)^{4/3} \leq 1/(\beta_0 T^{4/3}), \forall T \geq 2\), in (b) we use

\[
[x^\alpha]_i \triangleq \begin{cases} 
\lambda_{r+1,i}, & \text{if } i \in S_r; \\
0, & \text{otherwise.}
\end{cases}
\]

(112) and (118) as well as the facts that \(0 < \tau < 1\), \(\beta_r = \beta_0 r^{1/3}\), and \(\beta_0\) is a constant.

To further get an upper bound of \(\sum_{r=1}^{T} \frac{1}{\beta_r} \|G(x_r, \lambda_r)\|^2\), we notice that

\[
\left( \sum_{r=1}^{T} \frac{a_r}{\beta_r^3} \|\lambda_{r+1}\| \right)^2 \leq \left( \sum_{r=1}^{T} \beta_r^4 \right) \left( \sum_{r=1}^{T} \alpha_r^2 \|\lambda_{r+1}\|^2 \right) \leq \frac{1}{\beta_0^3} T^{-1/3} \Lambda \beta_0 T^{1/3} = \frac{\Lambda}{\beta_0^3}
\]

by applying the Cauchy-Schwarz inequality. Then, we can obtain

\[
\sum_{r=1}^{T} \frac{1}{\beta_r} \|G(x_r, \lambda_r)\|^2 \leq 4C \left( \Delta_F - \frac{2 \theta}{\beta_T \tau} \|\lambda''_{T+1} - \lambda_T'\|^2 + \left( 1 - \frac{3}{2} \tau + \frac{7}{2} \right) \frac{\beta_T}{\beta_T - 2} \right) \|\lambda_{T+1}\|^2 + \frac{2G(1 + 1/\theta')}{\beta_0 T^{2/3}(1 - \eta)} \left( \frac{2.5C + 4 \gamma_r}{\beta_r^3} \right) \|\lambda_{r+1}\|^2 \]

\[+ \frac{2.5C + 4 \gamma_r + 13C \theta \Lambda^{1/2}}{I_1} \frac{\Delta_{T+1}}{\beta_0^{3/2}} + \frac{2G(1 + 1/\theta')}{\beta_0 T^{2/3}(1 - \eta)} \right).
\]

For the case where \(\lambda_{T+1,i} > 0\), i.e., \(i \in S_r\), we have

\[
\|\lambda''_{T+1}\|^2 \leq \eta \|\lambda_T'\|^2 + \left( 1 + \frac{1}{\theta'} \right) \beta_r^2 \|g_+(x_{T+1})\|^2
\]

where (a) follows from (114), (27), and (118).
Therefore, we have

\[
\sum_{r=1}^{T} \frac{1}{\beta_r} \|G(x_r, \lambda_r)\|^2 \leq \frac{2\theta}{\beta r} \| \lambda_{r+1}^\theta - \lambda_r^\theta \|^2 + \left( \frac{1}{\beta r^2} - \frac{\tau^2}{\beta r} \right) \left( \eta \| \lambda_T^\theta \|^2 + \left( 1 + \frac{1}{\theta} \right) \beta^2 ||g_+((x_{T+1}))||^2 \right)
+ 4C \Delta_F + \left( \frac{2.5C + 4\tau + 13C \theta \lambda^{1/2}}{I_1} \right) \beta^3 \left( 1 - \eta \right) + \frac{8CG(1 + 1/\theta)^2}{\beta^2 (1 - \eta)}. \quad (224)
\]

Before showing the convergence of the optimality gap, we first verify the satisfaction of the functional constraints as follows.

**Stopping Criterion (Constraints)**

According to (13b) and (36), we know

\[
\| \lambda_{r+1}^g - \lambda_r^g \|^2 = \| \beta_r g_r(x_{r+1}) - \tau \lambda_r^g \|^2 = \sum_{i \in A_{r+1} \cap \mathcal{S}_r} \| \beta_r g_i(x_{r+1}) - \tau \lambda_r \|^2 - \sum_{i \in A_{r+1} \cap \mathcal{S}_r} \| \beta_r g_i(x_{r+1}) - \tau \lambda_r \|^2,
\]

which gives

\[
\sum_{i \in A_{r+1}} \| \beta_r g_i(x_{r+1}) - \tau \lambda_r \|^2 = \| \lambda_{r+1}^g - \lambda_r^g \|^2 + \sum_{i \in A_{r+1} \cap \mathcal{S}_r} \| \beta_r g_i(x_{r+1}) - \tau \lambda_r \|^2 \leq \| \lambda_{r+1}^g - \lambda_r^g \|^2 + \sum_{i \in A_{r+1} \cap \mathcal{S}_r} \| \beta_r g_i(x_{r+1}) - \tau \lambda_r \|^2 (228)
\]

\[
\leq \| \lambda_{r+1}^g - \lambda_r^g \|^2 + \sum_{i \in A_{r+1} \cap \mathcal{S}_r} 2 \| \beta_r (g_i(x_{r+1}) - g_i(x_r)) \|^2 + 2\tau^2 \| \lambda_r \|^2 (229)
\]

\[
\leq \| \lambda_{r+1} - \lambda_r \|^2 + 2L_g^2 \beta_r^2 \| x_{r+1} - x_r \|^2 + 2\tau^2 \| \lambda_r \|^2 (230)
\]

where (a) is true because of \( g_i(x_r) \leq 0, g_i(x_{r+1}) > 0, \forall i \in A_{r+1} \cap \mathcal{S}_r \), in (b) we apply Lipschitz continuity.

Note that

\[
\| \beta_r g_+((x_{r+1})) \|^2 - 2\beta_r \tau g_+((x_{r+1}), \lambda_r) + \tau^2 \| \lambda_r \|^2 = \| \beta_r g_+((x_{r+1})) - \tau \lambda_r \|^2 \leq \sum_{i \in A_{r+1}} \| \beta_r g_i((x_{r+1})) - \tau \lambda_r \|^2. \quad (231)
\]

Combining (230) and (231), we can have

\[
\| \beta_r g_+((x_{r+1})) \|^2 + \tau^2 \| \lambda_r \|^2 \\
\leq 2\beta_r \tau g_+((x_{r+1}), \lambda_r) + \| \lambda_{r+1} - \lambda_r \|^2 + 2L_g^2 \| x_{r+1} - x_r \|^2 + 2\tau^2 \| \lambda_r \|^2 \quad (232)
\]

\[
\leq \frac{1}{2} \| \beta_r g_+((x_{r+1})) \|^2 + 2\tau^2 \| \lambda_r \|^2 + \| \lambda_{r+1} - \lambda_r \|^2 + 2L_g^2 \beta_r^2 \| x_{r+1} - x_r \|^2 + 2\tau^2 \| \lambda_r \|^2 \quad (233)
\]

where we apply the Young’s inequality with parameter 2 to \( \beta_r \tau g_+((x_{r+1}), \lambda_r) \).

Then, by algebraic manipulation, we can obtain

\[
\| \beta_r g_+((x_{r+1})) \|^2 \leq 2\| \lambda_{r+1} - \lambda_r \|^2 + 4L_g^2 \beta_r^2 \| x_{r+1} - x_r \|^2 + 6\tau^2 \| \lambda_r \|^2. \quad (234)
\]
Dividing $\beta_r$ on both sides of the above inequality gives

$$
\beta_r \|g_+ (x_{r+1})\|^2
= \frac{1}{\beta_r} \|\beta_r g_+ (x_{r+1})\|^2
\leq \frac{2}{\beta_r} \|\lambda_{r+1} - \lambda_r\|^2 + 4L_g^2 \beta_r \|x_{r+1} - x_r\|^2 + \frac{6\tau^2}{\beta_r} \|\lambda_r\|^2
$$

where in (a) we use (41) and choose $\beta_0 \geq \sqrt{2L_g/\overline{U_j}}$ so that $2L_g^2/\beta_r \leq \frac{1}{\alpha_r}$.

Applying the telescoping sum, we can have

$$
\sum_{r=1}^{T} \beta_r \|g_+ (x_{r+1})\|^2
\leq 8C_1 \left( \Delta_F + \frac{2}{\beta_{T-1}} \|\lambda_{T+1}\|^2 \right) + \sum_{r=1}^{T} \left( \frac{5C_1}{\beta_r} \|\lambda_{r+1}\|^2 + \frac{26C_1\theta + 6\tau^2}{\beta_r} \|\lambda_r\|^2 \right)
\leq 8C_1 \left( \Delta_F + \frac{2}{\beta_{T-1}} \|\lambda_{T+1}\|^2 + \frac{5C_1}{\beta_T} \|\lambda_{T+1}\|^2 \right) + \sum_{r=1}^{T} \left( \frac{5C_1}{\beta_T} \|\lambda_{T+1}\|^2 + \frac{\Lambda \beta_0 ((5 + 26\theta)C_1 + 6\tau^2)}{\alpha_1 I_1} \left( \alpha_{0.2} T^{1/3} + \alpha_{0.3} T^{2/3} \right) \right)
$$

where in (a) we use

$$
\sum_{r=1}^{T} \frac{1}{\beta_r} \|\lambda_r\|^2 \leq \sum_{r=1}^{T} \frac{\alpha_{r+1}}{I_1} \|\lambda_r\|^2 \leq \frac{1}{\alpha_T I_1} \sum_{r=1}^{T} \alpha_{r+1} \|\lambda_r\|^2
\leq \Lambda \beta_0 T^{1/3} \left( \frac{\alpha_{0.2} + \alpha_{0.3} T^{1/3}}{\alpha_1 I_1} \right) \leq \frac{\Lambda \beta_0}{\alpha_1 I_1} \left( \alpha_{0.2} T^{1/3} + \alpha_{0.3} T^{2/3} \right) \sim \mathcal{O}(T^{2/3}),
$$

and in (b) we use (112).

Therefore, we have

$$
\left( \sum_{r=1}^{T} \beta_r \right)^{-1} \sum_{r=1}^{T} \beta_r \|g_+ (x_{r+1})\|^2 \leq 8C_1 \frac{\beta_0 T^{1/3}}{\beta_0 T^{4/3}} \left( \Delta_F + \frac{(4 + 5C_1) G (1 + \frac{1}{M}) T^{1/3}}{\beta_0 (1 - \eta)} \right) + \frac{\Lambda \beta_0 ((5 + 26\theta)C_1 + 6\tau^2)}{\alpha_1 I_1 \beta_0 T^{4/3}} \left( \alpha_{0.2} T^{1/3} + \alpha_{0.3} T^{2/3} \right),
$$
A Single-Loop Gradient Descent and Perturbed Ascent Algorithm for Nonconvex Functional Constrained Optimization

It is implied that combining (246) and (17) gives \( \lim_{T \to \infty} \| g_+(x_T) \|^2 = 0 \), meaning that the constraints are satisfiable. Based on the definition of \( T(\varepsilon) \) (we will use \( T \) as a shortcut of \( T(\varepsilon) \) in the following) in (19), we have

\[
\| g_+(x_{T+1}) \|^2 \leq \frac{8C_1 \left( \Delta_F + \frac{(4+5C_1)G(1+\frac{1}{\rho})T^{1/3}}{\beta_0(1-\eta)} \right) + \frac{\Delta \beta_0((5+26\vartheta)C_1+6\tau^2)}{\alpha_0,2/3}}{\alpha_0,2/3} \left( \alpha_0,2T^{1/3} + \alpha_0,3 T^{2/3} \right) \tag{247}
\]

\[
\leq \frac{8C_1 \Delta_F}{\beta_0 T^{1/3}} + \frac{8C_1(4+5C_1)G(1+\frac{1}{\rho})}{\beta_0^2(1-\eta)} + \frac{\Delta \beta_0((5+26\vartheta)C_1+6\tau^2)}{\alpha_0,1 I_1} + \frac{\Lambda((5+26\vartheta)C_1+6\tau^2)\alpha_0,3}{\alpha_0,1 I_1 T^{2/3}}. \tag{248}
\]

For convenience of expression, let

\[
C_{1,1} \triangleq \frac{8C_1 \Delta_F}{\beta_0}, \quad C_{1,2} \triangleq \frac{8C_1(4+5C_1)G(1+\frac{1}{\rho})}{\beta_0^2(1-\eta)} + \frac{\Delta \beta_0((5+26\vartheta)C_1+6\tau^2)}{\alpha_0,1 I_1}, \quad C_{1,3} \triangleq \frac{\Lambda((5+26\vartheta)C_1+6\tau^2)\alpha_0,3}{\alpha_0,1 I_1 T^{2/3}}. \tag{249}
\]

Then, when \( T \geq \text{max}\{C_{1,1}^{3/2}, C_{1,2}^{3/2}\} \), then we have

\[
\| g_+(x_{T+1}) \|^2 \leq \frac{2 + C_{1,2}}{T^{2/3}}. \tag{250}
\]

Next, we will get an upper bound of \(-\|\lambda''_{r+1} - \lambda'_r\|^2\) shown in (224) as follows:

\[
\| \lambda''_{r+1} - \lambda'_r \|^2 = \sum_{i \in S_r} (|\lambda_{r+1}|_i - |\lambda_r|_i)^2
\]

\[
= \sum_{i \in S_r \cap A_{r+1}} (|\lambda_{r+1}|_i - |\lambda_r|_i)^2 + \sum_{i \in S_r \setminus A_{r+1}} (|\lambda_{r+1}|_i - |\lambda_r|_i)^2 \tag{251}
\]

\[
\overset{\text{(27)}}{=} \sum_{i \in S_r \cap A_{r+1}} (|\lambda_{r+1}|_i - |\lambda_r|_i)^2 + \sum_{i \in S_r \setminus A_{r+1}} \tau^2 |\lambda_r|_i^2 \tag{252}
\]

\[
\overset{\text{(13b)}}{=} \sum_{i \in S_r \cap A_{r+1}} (\beta_r g_i(x_{r+1}) - \tau |\lambda_r|_i)^2 + \sum_{i \in S_r \setminus A_{r+1}} \tau^2 |\lambda_r|_i^2 \tag{253}
\]

\[
\overset{\text{(a)}}{=} \sum_{i \in S_r \cap A_{r+1}} (\tau^2 |\lambda_r|_i^2 + \beta_r^2 g_i^2(x_{r+1})) + \sum_{i \in S_r \setminus A_{r+1}} \tau^2 |\lambda_r|_i^2 \tag{254}
\]

\[
\geq \sum_{i \in S_r \cap A_{r+1}} \beta_r^2 g_i^2(x_{r+1}) + 2 \sum_{i \in S_r} \tau^2 |\lambda_r|_i^2 \geq 2 \tau^2 \| \lambda'_r \|^2 \tag{255}
\]

where in (a) we use the fact that both \( |\lambda_r|_i \) and \( g_i(x_{r+1}) \) are non-negative so we have

\[
(\beta_r g_i(x_{r+1}) - \tau |\lambda_r|_i)^2 = \tau^2 |\lambda_r|_i^2 - 2 \tau |\lambda_r|_i \beta_r g_i(x_{r+1}) + \beta_r^2 g_i^2(x_{r+1}) \geq \tau^2 |\lambda_r|_i^2 + \beta_r^2 g_i^2(x_{r+1}). \tag{256}
\]

To this end, we can have the upper bound of the optimality gap further based on the satisfaction of the functional constraints, i.e.,

\[
\sum_{r=1}^T \frac{1}{\beta_r} \| G(x_r, \lambda_r) \|^2 \leq -\frac{4 \Delta \vartheta}{\beta_0} \| \lambda'_r \|^2 + \left( \frac{1 - \frac{3}{\rho} \tau + \frac{\tau^2}{\rho^2}}{\beta_0} \right) \eta \| \lambda'_r \|^2 + \left( 1 + \frac{1}{\rho^2} \right) \beta_r T \| g_+(x_{T+1}) \|^2
\]

\[
+ 4C \Delta_F + \frac{2.5C + 4\vartheta + 13C \vartheta A^{1/2}}{I_1} + \frac{2.5C + 4\vartheta G(1 + 1/\theta')}{\beta_0^{3/2}} + \frac{2.5C + 4\vartheta G(1 + 1/\theta')}{\beta_0^{3/2}(1 - \eta)} + \frac{8CG(1 + 1/\theta')}{\beta_0 T^{2/3}(1 - \eta)}. \tag{257}
\]

From (250), we have

\[
\left( 1 + \frac{1}{\rho^2} \right) \beta_r T \| g_+(x_{T+1}) \|^2 \leq \left( 1 + \frac{1}{\rho^2} \right) \frac{2 + C_{1,2}}{\beta_0 T^{2/3}}. \tag{258}
\]
When \(4\vartheta r > \eta(1 - 3/2r + r^2/2)\), e.g., \(\vartheta = \eta(1 + r^2/2)/(4r)\), \(-\frac{4\vartheta r \lambda'_{x,r}^2}{\beta r} + \left(\frac{1 - 2r + r^2}{\beta r}\right)\eta\lambda'_{L,F}^2 \leq 0\). Combining Lemma 7, we can choose constant \(\vartheta\) as \(\max\{\eta(1 + r^2/2)/(4r), 1\}\).

**Step-sizes Selection:** GDPA only needs to tune two parameters for ensuring convergence. Regarding the step-size of the dual update, i.e., \(\beta_r\), we can choose it as \(\beta_r = \beta_0 r^{1/3}\) as discussed in the proof. From (134), (218), (236), we require

\[
\beta_0 \geq \max \left\{ \frac{2(1 - \tau)(\frac{2}{3} + U_J)}{\sigma} \sqrt{\frac{G(1 + \frac{1}{\beta})}{1 - \eta}}, \frac{1}{U_J} \sqrt{\frac{2Lg}{U_J}} \right\}, \quad (259)
\]

Then, we can consider \(\beta_0\) and choose the step-size of updating primal variable, i.e., \(\alpha_r\). Based on the discussion in the above proof, we choose it as \(\alpha_r = \frac{\alpha_0}{\alpha_{0, 2} + \alpha_{0, 3} r^{\tau/3}}\). From (41), (88), (205) we require

\[
\alpha_{0, 3} \geq \max \left\{ (1 - \tau) \sqrt{\frac{G(1 + \frac{1}{\beta})}{1 - \eta}} L_f + \beta_0 U_J L_g, 2(1 - \tau)L_g^2 + (8\vartheta L_g^2)/\tau^2 \beta_0 \right\}, \alpha_{0, 2} \geq L_f, \alpha_{0, 1} < 1, \quad (260)
\]

then conditions (41) and (88) can be satisfied while resulting in a consistent lower bound of \(\alpha_r\beta_r\) discussed in (215). Note that when \(r\) is larger than a constant, (205) is satisfied automatically. To be more specific, let \(C_2 = 13\max\{36, (64U_J)/U_g\}\) \(\vartheta/((1 - r)^2U_f^2/\beta_0)\). Then, when \(r \geq (C_2(\alpha_{0, 2} + \alpha_{0, 3})/\alpha_{0, 1})^{3/2}\), it can be easily verified that (205) holds.

**Stationarity (for both primal and dual variables):**

Therefore, we can obtain

\[
\sum_{r=1}^{T} \frac{1}{\beta_r} \|G(x_{r,r}, \lambda_r)\|^2 \leq 4C\Delta_F + \frac{2.5C + 4r + 13C\vartheta \Lambda_{1/2}}{I_1} \frac{\Lambda_{1/2}}{\beta_0^{3/2}} + \left(\frac{(2.5C + 4r)G}{\beta_0^2(1 - \eta)} + 2 + C_{1,2}\right), \quad (261)
\]

which leads to

\[
\|G(x_T, \lambda_T)\|^2 \\
\leq \left(\sum_{r=1}^{T} \frac{1}{\beta_r}\right)^{-1} \sum_{r=1}^{T} \frac{1}{\beta_r} \|G(x_{r,r}, \lambda_r)\|^2 \\
\leq 4C\Delta_F \frac{\Lambda_{1/2}}{\beta_0^{3/2}} + \frac{2.5C + 4r + 13C\vartheta \Lambda_{1/2}}{I_1} \frac{\Lambda_{1/2}}{\beta_0^{5/2}T^{3/2}} + \left(\frac{(2.5C + 4r)G}{\beta_0^2(1 - \eta)} + 2 + C_{1,2}\right) \frac{(1 + 1/\theta')}{\beta_0 T^{3/2}} + \frac{8CG(1 + 1/\theta')}{\beta_0 T^{3/2}(1 - \eta)}, \quad (262)
\]

\[
\sim O\left(\frac{1}{T^{2/3}}\right), \quad (263)
\]

or equivalently \(\|G(x_T, \lambda_T)\| \sim O(T^{-1/3})\).

**Feasibility (constraint violation):**

From (246), we know

\[
\|\beta_T g_+(x_T)\|^2 \leq \left(\sum_{r=1}^{T} \frac{1}{\beta_r}\right)^{-1} \sum_{r=1}^{T} \frac{1}{\beta_r} \|\beta_r g_+(x_r)\|^2 \\
\leq \frac{8C_1}{\beta_0^{3/2}} \left(\Delta_F + \frac{(4 + 5C_1)G}{\beta_0(1 - \eta)} \frac{T^{1/3}}{I_1} \right) + \frac{\Lambda_{1/2}(5 + 26\vartheta)C_1 + 6r^2}{\alpha_{0,2} I_1 \beta_0 T^{2/3}} \left(\alpha_{0,2} T^{1/3} + \alpha_{0,3} T^{2/3}\right) \quad (265)
\]

\[
\leq \alpha_{0,3} \lambda_0 (5 + 26\vartheta)C_1 + 6r^2 \frac{\alpha_{0,1} I_1 \beta_0}{\alpha_{0,1} I_1 T^{1/3}} + \frac{8C_1(4 + 5C_1)G}{\alpha_{0,2} I_1 T^{1/3}} \frac{(1 + 1/\theta)}{\beta_0^2(1 - \eta) T^{3/2}} + \frac{8C_1 \Delta_F}{\beta_0 T^{3/2}} \quad (266)
\]
which directly gives
\[ \|g_+(x_T)\|^2 \leq \frac{\alpha_0 \lambda_0 ((5 + 26 \theta)C_1 + 6 \tau^2)}{\alpha_0, \lambda_0 I_1 \beta_0^2 T^{2/3}} + \frac{\alpha_0 \lambda_0 ((5 + 26 \theta)C_1 + 6 \tau^2)}{\alpha_0, \lambda_0 I_1 T} + 8C_1 (4 + 5C_1) G (1 + \frac{1}{\beta_0^3}) + 8C_1 \Delta_F \frac{1}{\beta_0} (1 - \eta)^T \sim \mathcal{O} \left( \frac{1}{T^{2/3}} \right), \tag{267} \]
or equivalently \( \|g_+(x_T)\| \sim \mathcal{O}(T^{-1/3}). \)

**Slackness:**

Let \( m \) denote the number of constraints or dimension of \( \lambda_r \). Then, when \( [\lambda_r]_i = 0 \) then \( [\lambda_r], g_i(x_r) = 0. \) Otherwise, \( [\lambda_r]_i > 0, \) and
\[
[\lambda_r], g_i(x_r) \leq \frac{1}{\beta_r} \left( \frac{\|\lambda_r - \lambda_{r-1}\|^2}{2} + \frac{\|\lambda_{r-1}\|^2}{2} + \|\lambda_r\|^2 \right),
\]
so we have
\[
\sum_{r=1}^{m} \|\lambda_r\| g_i(x_r) \leq \frac{1}{\beta_r} \left( \frac{\|\lambda_r - \lambda_{r-1}\|^2}{2} + \frac{\|\lambda_{r-1}\|^2}{2} + \|\lambda_r\|^2 \right). \tag{270}
\]

Therefore, we can conclude that
\[
\sum_{i=1}^{m} \left| [\lambda_r], g_i(x_T) \right| \leq \left( \sum_{i=1}^{m} \frac{1}{\beta_r} \right)^{-1} \left( \sum_{i=1}^{m} \frac{1}{\beta_r} \left| [\lambda_r], g_i(x_r) \right| \right) \leq \left( \sum_{i=1}^{m} \frac{1}{\beta_r} \right)^{-1} \left( \frac{\|\lambda_r - \lambda_{r-1}\|^2}{2} + \frac{\|\lambda_{r-1}\|^2}{2} + \|\lambda_r\|^2 \right) \leq \mathcal{O}(T^{-1/3}). \tag{271}
\]

**E. Proofs for the Auxiliary Lemmas**

**E.1. Proof of Lemma 1 (Approximate Farkas Lemma)**

**Proof.** We first need to show that the two cases cannot hold simultaneously. Since \( g + \Delta \in \mathcal{K} \), there exits vectors \( y \geq 0 \) and \( w \) such that \( g + \Delta = B y + C w \). If there also existed a \( d \) satisfying (21), then we have by taking inner products that
\[
-\epsilon \geq d^T g = d^T B y + d^T C w = (B^T d)^T y + d^T C w = (C^T d)^T w \tag{272}
\]
where in (a) we use \( C^T d = 0, B^T d \geq 0, y \geq 0, \) and in (b) we use \( \|\Delta\| \leq \epsilon \) and \( \|d\| = 1 \). Therefore, it is obvious that both cases cannot be holding at once.

Next, we will show that one of the two cases holds, i.e., we show that how to construct a vector \( d \) such that it satisfies (21) in the case that \( g + \Delta \notin \mathcal{K} \). Let \( s^* \) be a vector in \( \mathcal{K} \) which is closest to \( g \), i.e.,
\[
s^* = \arg \min_{s \in \mathcal{K}} \| z - (g + \Delta) \|^2. \tag{274}
\]
So, we have
\[
\langle s^* - (g + \Delta), s - s^* \rangle \geq 0, \forall s \in \mathcal{K} \tag{275}
\]
by applying the optimality condition of (274). Note that since \( s \in K \) and \( K \) is a cone, \( \alpha s \in K \) for all scalars \( \alpha \geq 0 \). Since \( \|\alpha s^* - (g + \Delta)\|_2^2 \) is minimized by \( \alpha = 1 \), we have \( (s^*)^T(s^* - (g + \Delta)) = 0 \). Combing with (275), we have
\[
s^T(s^* - (g + \Delta)) \geq 0, \forall s \in K. \tag{276}
\]
Define \( d = s^* - (g + \Delta) \) satisfying (275). From (276), we have that \( d^T s \geq 0, \forall s \in K \), so
\[
d^TBy + Cw \geq 0, \quad \forall w, y \geq 0. \tag{277}
\]
In the following, we will verify that \( d \) satisfies all the relations shown in (21).

1. Verify (21a)
   Note that \( d \neq 0 \) because \( (g + \Delta) \notin K \). From the fact that \( (s^*)^T(s^* - (g + \Delta)) = 0 \), we have
\[
d^T(g + \Delta) = d^T(s^* - d) = (s^* - (g + \Delta))^T s^* - d^T d = -\|d\|_2^2, \tag{278}
\]
which is
\[
d^T g = -d^T \Delta - \|d\|_2^2 = -(s^* - (g + \Delta))^T \Delta - \|d\|_2^2 \overset{(a)}{\leq} -\|d\|_2^2 < -\epsilon \tag{279}
\]
where (a) holds since \( \Delta \in K \) and (276), and (b) is true because \( \|d\| = 1 \) and \( 0 < \epsilon < 1 \).

2. Verify (21b) \(^2\)
   From (277), we have that \( (C^T d)^T \geq 0, \forall w \) when \( y = 0 \), which is true only if \( C^T d = 0 \).

3. Verify (21c)
   Similar as the previous case, we have that \( (Bd)^T y \geq 0, \forall y \geq 0 \), which is true only if \( B^T d \geq 0 \).

In summary, we have shown that the constructed \( d \) satisfies all the properties, which completes the proof. \( \square \)

### E.2. Proof of Proposition 1

Without of generality, we give the following lemma to show the relation between \( \|1/\alpha[x - \text{proj}_\mathcal{X}(x - \alpha\nabla_L(x, \lambda))]\| \leq \epsilon, \alpha > 0 \) and (20a).

**Lemma 9.** Let feasible set \( \mathcal{X} \) be represented by differentiable continuous convex functions \( c_i(x), \forall i \) defined by
\[
c_i(x) = 0, \quad i \in \mathcal{E}, \quad \text{and} \quad c_i(x) \leq 0, \quad i \in \mathcal{I}, \tag{280}
\]
where \( \mathcal{E} \) denotes the set of the indices of equality constraints, and \( \mathcal{I} \) denotes the set of the indices of inequality constraints. When \( \|\mathcal{G}(x^*, \lambda^*)\| \leq \epsilon \), i.e.,
\[
\frac{1}{\alpha} \|x^* - \text{proj}_\mathcal{X}(x^* - \alpha\nabla_L(x^*, \lambda^*))\| \leq \epsilon, \quad \forall \alpha > 0 \tag{281}
\]
then, we have
\[
\text{dist} (\nabla L(x^*, \lambda^*), -\mathcal{N}_\mathcal{X}(x^*)) \leq \epsilon' \tag{282}
\]
where \( \epsilon' \) has a one-to-one correspondence of \( \epsilon \) and also \( \epsilon' \sim \mathcal{O}(\epsilon) \).

**Proof.** From Lemma 3 in (Lu et al., 2020), we know that (281) implies
\[
\langle \nabla L(x^*), x - x^* \rangle \geq -\epsilon', \quad \forall x \in \mathcal{X}. \tag{283}
\]
when \( \mathcal{X} \) is bounded and there is a one-to-one correspondence of \( \epsilon' \) and \( \epsilon \) in the sense that \( \epsilon' \sim \mathcal{O}(\epsilon) \). \( \square \)

\(^2\)Verifying (21b) and (21c) is identical to the original proof of the Farkas lemma (Please see Lemma 12.4 in (Nocedal and Wright, 2006)) since the two relations do not include any perturbation (approximate) term.
Define a cone
\[ K = \left\{ \sum_{i \in A'(x^*')} -\mu_i \nabla c_i(x^*), \mu_i \geq 0 \quad \text{for} \ i \in A'(x^*) \cap I \right\} \] (284)
where \( A'(x) \) denotes the set of active constraints at point \( x^* \).

Let \( g = \nabla L(x^*, \lambda^*) \). From Lemma 1 (approximate Farkas lemma), we have that either
\[ \nabla L(x^*, \lambda^*) + \Delta = -\sum_{i \in A'(x^*)} \mu_i \nabla c_i(x^*), \quad \mu_i \geq 0 \quad \text{for} \ i \in A'(x^*) \cap I, \] (285)
which is equivalent to
\[ \left\| \nabla L(x^*, \lambda^*) + \sum_{i \in A'(x^*)} \mu_i \nabla c_i(x^*) \right\| \leq \epsilon', \quad \mu_i \geq 0 \quad \text{for} \ i \in A'(x^*) \cap I \] (286)
or else there is a direction \( d \) such that \( d^T \nabla L(x^*, \lambda^*) < -\epsilon' \) and \( d \in F(x^*) \) and \( \|d\| = 1 \), where
\[ F(x) = \left\{ d \left| \begin{array}{l} d^T \nabla c_i(x) = 0, \quad \forall i \in E \\ d^T - \nabla c_i(x) \geq 0, \quad \forall i \in A'(x) \cap I \end{array} \right\} \] (287)
denotes the cone of linearized feasible directions.

Due to the fact that \( c_i(x), \forall i \) are convex, we have
\[ \sum_{i \in A'(x^*)} \mu_i c_i(y) \geq \sum_{i \in A'(x^*)} \mu_i c_i(x^*) + \sum_{i \in A'(x^*)} \mu_i \nabla^T c_i(x^*)(y - x^*), \forall c_i(y) \leq 0, i \in A'(x^*) \cap I. \] (288)

Since \( c_i(y) \leq 0 \), it is obvious that
\[ -\sum_{i \in A'(x^*)} \mu_i c_i(x^*) \geq \sum_{i \in A'(x^*)} \mu_i \nabla^T c_i(x^*)(y - x^*), \quad \text{for} \ c_i(y) \leq 0, i \in A'(x^*) \cap I. \] (289)

Also, since \( i \in A'(x^*) \cap I \), we have \( c_i(x^*) = 0 \), i.e., \( x^* \notin \text{int}(\mathcal{X}) \). Therefore, the above (289) further yields the following inequality:
\[ 0 \geq \sum_{i \in A'(x^*)} \mu_i \nabla^T c_i(x^*)(y - x^*), \quad \text{for} \ c_i(y) \leq 0, i \in A'(x^*) \cap I, x^* \notin \text{int}(\mathcal{X}) \] (290)

By the definition of the normal cone, we have from (290) that
\[ \mathcal{N}_{\mathcal{X}}(x^*) = \left\{ \begin{array}{ll} \sum_{i \in A'(x^*)} \mu_i \nabla c_i(x^*), & \mu_i \geq 0, \text{for} \ i \in A'(x^*) \cap I, x^* \notin \text{int}(\mathcal{X}); \\
\{0\}, & \text{otherwise.} \end{array} \right\} \] (291)

Combining the facts (283) and (286) directly gives the result (282). \( \square \)

Since we assume that \( \mathcal{X} \) is convex, directly applying Lemma 9 gives proposition 1.
F. Additional Numerical Experiments

We perform the numerical experiments on a machine with Intel(R) Core(TM) i5-8265U CPU @ 1.60GHz 1.80GHz.

F.1. More Details of the Experimental Settings in the Main Text

mNPC problem. We take $m = 3$, $\lambda = 1$, and $r_j = 0.1$, $\forall j$. The initial points of all the algorithms are the same, and $x_0$ is randomly generalized, where each entry follows i.i.d. Gaussian distribution $CN(0, 1 \times 10^{-3})$. Note that the regularity condition in this problem can be verified, since the sigmoid function is monotonic. We add i.i.d. Gaussian noise directly to each data with zero mean and unit variance. The initial step-sizes of GDPA are chosen as $\alpha_0 = 0.1$, $\beta_0 = 1 \times 10^{-4}$, and $\tau = 0.1$. The initial dual variable of IALM is $\gamma_0 = 1 \times 10^{-2}$, and the initial penalty parameter of IPPP is $1 \times 10^{-3}$. For the inner loops of IALM and IPPP, we just use the standard Nesterov’s accelerated gradient descent with step-size $0.01$ and momentum parameter $0.1$. For the inner loop of IQRC, the initial step-size is set as $\gamma_0 = 0.1$, the maximum number of the inner loop is $30$, and the predefined feasibility tolerance is $1$.

Neural nets training with budget constraints. The initial step-sizes of GDPA are chosen as $\alpha_0 = 2 \times 10^{-4}$, $\beta_0 = 2 \times 10^{-4}$, and $\tau = 0.1$. The initial dual variable of IALM is $\gamma_0 = 1 \times 10^{-3}$, and the initial penalty parameter of IPPP is $1 \times 10^{-4}$. For the inner loops of IALM and IPPP, we use the standard Nesterov’s accelerated gradient descent with step-size $1 \times 10^{-4}$ and momentum parameter $0.1$. For the inner loop of IQRC, the initial step-size is set as $\gamma_0 = 1 \times 10^{-4}$, the maximum number of the inner loop is $30$, and the predefined feasibility tolerance is $0.01$. The neural net includes two layers, where the hidden layer has $30$ neurons, the output dimension of the perception layer is $10$, and the activation function is sigmoid.

F.2. CMDP

We use the code shared in (Bhandari and Russo, 2019) and extend it to CMDP problems for testing the performance of GDPA, where $|S| = 50$, $|A| = 10$ and $\gamma = 0.9$. The initial step-sizes of GDPA is $1 \times 10^3$, $0.5$, and $\tau = 0.1$. We set the constraints thresholds as $b = 6$, $7$, $8$ for three cases. Comparing the classic policy gradient (PG) method, it can be seen in Figure 4 that GDPA can provide the solutions that achieve the predefined constrained rewards while PG fails. Also, it can be observed that if the predefined constrained reward is higher, then the achieved objective rewards will be lower, which makes sense since CMDP is a more complex learning task with multiple optimization objectives than the case without constraints.

![Figure 4. Objective reward v.s. constrained reward achieved by GDPA and PG.](image-url)
