Abstract. A heteroclinic network exhibits infinite switching if each infinite sequence of
admissible heteroclinic trajectories may be shadowed. Under a set of checkable hypotheses,
we describe a class of vector fields exhibiting abundant switching near a network: there exists
a set of initial conditions with positive Lebesgue measure realising infinite switching.
The proof relies on the existence of “large” strange attractors in the terminology of Broer,
Simó and Tatjer (Nonlinearity, 667–770, 1998) near a heteroclinic tangle unfolding an attract-
ning network containing a two-dimensional heteroclinic connection. For our class of vector
fields, any small non-empty open ball of initial conditions realizes infinite switching. We
illustrate the theory with a specific one-parameter family of differential equations, for which
we are able to characterise its global dynamics for almost all parameters.

1. Introduction

A heteroclinic cycle is a set of finitely many invariant saddles and trajectories connecting
them in a cyclic way. A connected union of finitely many heteroclinic cycles is what we
call a heteroclinic network. These structures are associated with intermittent behaviour and
are used to model intermittency dynamics in several applications, including neuroscience,
nonlinear oscillations, geophysics, game theory and populations dynamics – see for instance
the references [1, 2, 3, 7, 25]. The study of heteroclinic cycles and networks is well-established
as an autonomous subject in the dynamical systems community [16].

The present article contributes to the latter by investigating a particular type of complicated
dynamics in a neighbourhood of a heteroclinic network unfolding another containing a

two-dimensional connection. This configuration often occurs in $\mathbb{S}\mathbb{O}(2)$ and $\mathbb{S}\mathbb{O}(3)$-equivariant differential equations. There are different types of switching, leading to increasingly complex behaviour:

- **switching at a saddle**[3] characterised by the existence of initial conditions near an incoming connection to that saddle, whose trajectory follows any of the possible outgoing connections. Incoming connection does not predetermine the outgoing choice at the saddle.

- **switching along a heteroclinic connection**[3] which extends the notion of switching at a saddle to initial conditions whose solutions follow a prescribed homo/heteroclinic connection.

- **infinite switching**[3, 4, 5, 15, 17, 25], which ensures that any infinite sequence of connections in the network is a possible path near the network. This is different from **random switching** in which trajectories shadow the network in a non-controllable way[24].

The absence of switching along a connection prevents infinite switching. Kirk and Silber[18] studied a network consisting of two cycles and trajectories are allowed to change from a neighbourhood of one cycle to a neighbourhood of the other cycle. Despite both cycles are numerically observable, there is no sustained switching in this example: an orbit may switch from one cycle to the other initially but might not switch back again. This behaviour is referred as switching, although it is a very weak example of this phenomenon. In[10], the expression railroad switching is used in relation to switching at a saddle.

The authors of[24] find a form of complicated switching leading to regular and irregular cycling near a network. It is also worth to see the reference[11] where the authors study two examples of networks with rich dynamics without infinite switching. Complex behaviour near a network can also arise from the presence of noise-induced switching, but we do not address the presence of noise in the present research article.

At this moment, it would be convenient to distinguish between Lyapunov-stable networks from the unstable ones. In the first case, the authors of[15, Th. 2.1] and[14, 28] proved the existence of forward infinite switching near a homoclinic network: solutions shadow any infinite sequence of connections while approaching the network. In these cases, there is neither backward switching nor suspended horseshoes near the network. For stable networks in three-dimensions involving saddle-foci, the existence of a set of initial conditions with positive Lebesgue measure realising infinite switching is relatively straightforward.

In[19], the authors have studied an example in which solutions near a heteroclinic network switch between excursions about different cycles. Chaotic switching seems to occur whether or not the network is asymptotically stable – it seems an “intermediate” case of stability. The mechanism for switching is the presence of a pair of complex eigenvalues in the linearisation of the flow about one of the equilibria in the network. If $\delta^{\text{min}} < 1 < \delta^{\text{max}}[2]$ then whether or not an individual trajectory approaches the network or diverges from it depends on the detailed itinerary of that trajectory. Most trajectories seem to be attracted to a chaotic or periodic attractor some small distance away from the network. The whole network structure are observed in the long term dynamics of the system even though the network is unstable.

---

1 Also called switching at a node.

2 See Section 3.2 of[19] for the precise definition of these two values.
As far as we know, there is not a formal proof of the existence of a chaotic attractor near the network studied in [19].

In this paper, we concentrate our attention on unstable networks, where forward and backward switching seem to be the consequence of hyperbolic suspended horseshoes in the neighbourhood of the network – [15, Th. 2.2], [21, Prop. 2] and [15, 17, 25, 26]. Since these hyperbolic horseshoes have zero Lebesgue measure(3), for unstable networks we know nothing about the Lebesgue measure of the set of initial conditions that realize infinite switching. Theoretically infinite switching might not be observable.

**Novelty:** In this paper, we describe a class of vector fields exhibiting abundant switching near a network, i.e. there exists a set of initial conditions with positive Lebesgue measure realizing infinite switching. Our proof relies on the existence of “large” strange attractors in the terminology of [8] near a heteroclinic tangle unfolding an attracting network with a continuum of connections. We prove that any small ball of initial conditions realizes infinite switching. Our main results have been partially motivated by the numerics of [27] and the ideas of [19 §3.2] and [8 §5.3.3].

**Summary:** In Table 1 we summarize the main results in the literature about infinite switching and their dynamical mechanisms. We choose to mention only the paradigmatic references in the literature for clarity and the choice has been based on our personal preferences. The reader interested in further detail and/or more examples can use the references within those we mention. We have not included the work [17] because their network cannot be reduced to a three-dimensional center manifold, although it contains very complex dynamics involving switching.

**Structure of this article.** The rest of this paper is organised as follows. For reader’s convenience, we have compiled in Section 2 a list of basic definitions. In Section 3 we describe precisely our object of study, we review the literature related to it and we state the main results of the article. The coordinates and other notation are presented in Section 4. After reducing the dynamics of the 2-dimensional first return map to the dynamics of a 1-dimensional map in Section 6, we collect the main ideas of [31] about a precise family of circle maps with singularities in Section 7. These results are refined in Section 8.

The proof of Theorems A and B are performed in Sections 9 and 10, respectively. We perform illustrative computer experiments using Matlab (R2021b, Mathworks, Natick, MA, USA) for an explicit family of vector fields in Section 11. Finally, in Section 12 we relate our results with others in the literature, emphasizing the role of the twisting number.

We have endeavoured to make a self contained exposition bringing together all topics related to the proofs. We revive some useful results from the literature; we hope this saves the reader the trouble of going through the entire length of some referred works to achieve a complete description of the theory. We have drawn illustrative figures to make the paper easily readable.

2. Preliminaries

In this section, we introduce some terminology for vector fields acting on \(\mathbb{R}^4\) that will be used in the remaining sections. For \(\varepsilon > 0\) small enough, consider the one-parameter family

\[^3\text{We assume the initial vector field has sufficient regularity in such a way that hyperbolic invariant sets have zero Lebesgue measure.}\]

Table 1. Overview of the results in the literature about infinite switching and the contribution of the present article (in blue). The concepts of stable and unstable rely on the Lyapunov stability.

of $C^3$-smooth autonomous differential equations

$$\dot{x} = g_{\lambda}(x), \quad x \in S^3 \subset \mathbb{R}^4 \quad \lambda \in [0, \varepsilon]$$

(2.1)

where $S^3$ denotes the three-dimensional unit sphere endowed with the usual topology. Denote by $\varphi_{\lambda}(t, x), t \in \mathbb{R}$, the flow associated to (2.1). The flow is complete (all solutions are defined for all $t \in \mathbb{R}$) because $S^3$ is a boundaryless compact set. For $n \in \mathbb{N}$, throughout the article, let us denote by $\text{Leb}_n$ the usual Lebesgue measure of borelian subsets of $\mathbb{R}^n$. 
2.1. **Attracting set.** A subset $\Omega$ of $S^3$ for which there exists a neighbourhood $U \subset S^3$ satisfying $\varphi_\lambda(t,U) \subset U$ for all $t \in \mathbb{R}_0^+$ and

$$
\bigcap_{t \in \mathbb{R}_0^+} \varphi_\lambda(t,U) = \Omega
$$

is called an *attracting set* by the flow of (2.1); it is not necessarily connected. Its basin of attraction, denoted by $B(\Omega)$, is the set of points in $S^3$ whose orbits have $\omega$—limit in $\Omega$. In this article, we say that $\Omega$ is *asymptotically stable*, or that $\Omega$ is a global attractor, if $B(\Omega) = S^3$.

2.2. **Heteroclinic structures.** Suppose that $P_1$ and $P_2$ are two hyperbolic saddle-foci of (2.1). There is a *heteroclinic cycle* associated to $P_1$ and $P_2$ if

$$W^u(P_1) \cap W^s(P_2) \neq \emptyset \quad \text{and} \quad W^u(P_2) \cap W^s(P_1) \neq \emptyset.$$ 

For $i,j \in \{1,2\}$, the non-empty intersection of $W^u(O_i)$ with $W^s(O_j)$ is called a *heteroclinic connection* from $O_i$ to $O_j$, and will be denoted by $[O_i \to O_j]$; this set may be either a single trajectory or a union of trajectories (continua of connections [7]). A *heteroclinic network* is a connected union of heteroclinic cycles. Although heteroclinic cycles involving equilibria are not a generic feature within differential equations, they may be structurally stable within families of systems which are equivariant under the action of a compact Lie group due to the existence of flow-invariant subspaces.

2.3. **Lyapunov exponents.** A *Lyapunov exponent* may be seen as an average exponential rate of divergence or convergence of nearby trajectories in the phase space. Let $M$ be a compact, connected and smooth Riemannian two-dimensional manifold and $f : M \to M$ a diffeomorphism. By the Oseledeets’ Theorem, for Lebesgue almost points $x \in M$, there is a splitting

$$
T_x M = E^1_x \oplus E^2_x,
$$

(called the *Oseledeets’ splitting*) and real numbers $\lambda_1(x) \geq \lambda_2(x)$ (called *Lyapunov exponents*) such that $Df(x)(E^1_x) = E^1_{f(x)}$ and $Df(x)(E^2_x) = E^2_{f(x)}$ and

$$
\lim_{n \to \pm \infty} \frac{1}{n} \log \|Df^n(x)(v^j)\| = \lambda_j(f,x)
$$

for any $v^j \in E^j_x \setminus \{0\}$, $j = 1,2$, where $\| \cdot \|$ denotes the euclidean norm in $M$. For $x \in M$, if either $\lambda_1(f,x) > 0$ or $\lambda_2(f,x) > 0$, then one has exponential divergence of nearby orbits. In this case, we say that there exists an orbit with a *positive Lyapunov exponent*. The presence of exponential orbital divergence implies that trajectories whose initial conditions are hard to be distinguished will soon depart, and most likely behave afterwards quite differently.

2.4. **“Large” strange attractor.** Based on [8], we define “large” strange attractor. For $\varepsilon > 0$, a *large strange attractor* of a two-dimensional dissipative diffeomorphism defined on an annulus parametrized by $[0,2\pi] \times [0,\varepsilon]$ [3], is a compact invariant set $\Lambda$ with the following properties:

1. the basin of attraction of $\Lambda$ contains a non-empty open set (and thus has positive Lebesgue measure);

---

1. If $\lambda_1 \in \mathbb{C} \setminus \mathbb{R}$, then $\lambda_2 = \overline{\lambda_1}$ and $E^1_x \equiv E^2_x$ is a two-dimensional set.

2. The first component is the angular coordinate where 0 is identified with $2\pi$ and the second component is the height component. This set is also called by circloid.
(2) there is a dense orbit in \( \Lambda \) with a positive Lyapunov exponent (\( \Leftrightarrow \) exponential growth of the derivative along its orbit);

(3) the strange attractor winds around the whole annulus \([0, 2\pi] \times [0, \varepsilon]\).

A vector field possesses a “large” strange attractor if the first return map to an annular cross-section does.

2.5. **Infinite (forward) switching.** Let \( \Gamma \) be a heteroclinic network associated to \( \{O_1, \ldots, O_n\} \), a set of \( n \) invariant saddles, where \( n \in \mathbb{N} \).

**Definition 1.** If \( k \in \mathbb{N} \), a \textit{finite path of order} \( k \) on \( \Gamma \) is a sequence \( \{\gamma_1, \ldots, \gamma_k\} \) of heteroclinic connections in \( \Gamma \) such that \( \gamma_i \subset W^u(O_j) \cap W^s(O_{j+1}) \) for all \( i \in \{1, \ldots, k\} \) and \( j \in \{1, \ldots, n\} \).

We use the notation \( \sigma^k = \{\sigma(1), \ldots, \sigma(k)\} \) for this type of finite path. For an \textit{infinite path}, take \( k \in \mathbb{N} \) and denote it by \( \sigma^\infty \).

Let \( N_{\Gamma} \) be a neighbourhood of the network \( \Gamma \) and let \( W_j \subset N_{\Gamma} \) be a neighbourhood of \( O_j, j \in \{1, \ldots, n\} \). For each heteroclinic connection \( \gamma_i \) in \( \Gamma \), consider a point \( p_i \in \gamma_i \) and a neighbourhood \( V_i \subset N_{\Gamma} \) of \( p_i \). The collection of these neighbourhoods should be pairwise disjoint.

**Definition 2.** Given neighbourhoods as above, for \( k \in \mathbb{N} \), we say that the trajectory of a point \( q \in S^3 \) follows the \textit{finite path of order} \( k \), say \( \sigma^k \), if there exist two monotonically increasing sequences of times \( (t_j)_{j \in \{1, \ldots, k\}} \) and \( (z_j)_{j \in \{1, \ldots, k-1\}} \) such that for all \( j \in \{1, \ldots, k-1\} \), we have \( t_j < z_j < t_{j+1} \) and:

\[
\begin{align*}
(\text{i}) & \quad \varphi_\lambda(t, q) \subset N_{\Gamma} \text{ for all } t \in ]t_1, t_k[; \\
(\text{ii}) & \quad \varphi_\lambda(t_j, q) \in W_j \text{ for all } j \in \{1, \ldots, k\} \text{ and } \varphi_\lambda(z_j, q) \in V_{\sigma(j)} \text{ for all } j \in \{1, \ldots, k\}; \\
(\text{iii}) & \quad \text{for all } j = 1, \ldots, k-1 \text{ there exists a proper subinterval } I \subset ]z_j, z_{j+1}[ \text{ such that, given } t \in ]z_j, z_{j+1}[, \varphi_\lambda(t, q) \in V_j \text{ if and only if } t \in I.
\end{align*}
\]

The notion of a trajectory following an infinite path can be stated similarly. Along the paper, when we refer to points that follow a path, we mean that their trajectories do it. Based on [5, 25], we define:

**Definition 3.** There is:

\[
\begin{align*}
(\text{i}) & \quad \text{finite switching of order } k \text{ near } \Gamma \text{ if for each finite path of order } k, \text{ say } \sigma^k, \text{ and for each neighbourhood } N_{\Gamma}, \text{ there is a trajectory in } N_{\Gamma} \text{ that follows } \sigma^k \text{ and } \\
(\text{ii}) & \quad \text{infinite forward switching (or simply switching) near } \Gamma \text{ by requiring that for each infinite path and for each neighbourhood } N_{\Gamma}, \text{ there is a trajectory in } N_{\Gamma} \text{ that follows it.}
\end{align*}
\]

In general, switching is defined for positive time; this is why it is called by \textit{forward switching}. We may define analogously \textit{backward switching} by reversing the direction of the variable \( t \in \mathbb{R} \).

An infinite path on \( \Gamma \) can be considered as a pseudo-orbit of \([2,1]\) with infinitely many discontinuities. Switching near \( \Gamma \) means that any pseudo-orbit in \( \Gamma \) can be realized. In [15], using \textit{connectivity matrices}, the authors gave an equivalent definition of switching, emphasising the possibility of coding all trajectories that remain in a given neighbourhood of the network in both finite and infinite times.
Definition 4. We say that system (2.1) exhibits abundant infinite switching near $\Gamma$ if there is infinite switching near $\Gamma$ and this phenomenon may be realized by a set of initial conditions with positive Lebesgue measure.

3. Setting and Main results

In this section, we enumerate the main assumptions concerning the configuration of our network and we state the main results of the article.

3.1. Starting point. For $\varepsilon > 0$ small enough and $r \geq 3$, consider the one-parameter family of $C^r$–smooth differential equations (endowed with the usual $C^r$–topology):

$$\dot{x} = g_\lambda(x) \quad x \in S^3 \quad \lambda \in [0, \varepsilon]$$

satisfying the following hypotheses for $\lambda = 0$:

(H1) There are two different equilibria, say $P_1$ and $P_2$.

(H2) The eigenvalues of $Dg_0(X)$ are:

(H2a) $E_1$ and $-C_1 \pm \omega_1 i$ where $C_1 > E_1 > 0$, $\omega_1 > 0$, for $X = P_1$;

(H2b) $-C_2$ and $E_2 \pm \omega_2 i$ where $C_2 > E_2 > 0$, $\omega_2 > 0$, for $X = P_2$.

The equilibrium $P_1$ has a 2-dimensional stable and 1-dimensional unstable manifold that will be denoted by $W^s(P_1)$ and $W^u(P_1)$, respectively. In a similar way, $P_2$ has a 1-dimensional stable and 2-dimensional unstable manifold and the terminology is $W^s(P_2)$ and $W^u(P_2)$. For $M \subset S^3$, denoting by $\overline{M}$ the topological closure of $M$, we also assume that:

(H3) The manifolds $\overline{W^u(P_2)}$ and $\overline{W^s(P_1)}$ coincide and $\overline{W^u(P_2)} \cap \overline{W^s(P_1)}$ consists of a two-sphere (continuum of connections).

(H4) There are two trajectories, say $\gamma_1, \gamma_2$, contained in $W^u(P_1) \cap W^s(P_2)$, one in each connected component of $S^3 \setminus \overline{W^u(P_2)}$ (the one-dimensional connections).

For $\lambda = 0$, the two equilibria $P_1$ and $P_2$, the two-dimensional heteroclinic connection from $P_2$ to $P_1$ referred in (H3) and the two trajectories listed in (H4) build a heteroclinic network which we denote by $\Gamma$. This network has an attracting character:

Lemma 3.1 ([21] [23]). The network $\Gamma$ is a global attractor and does not exhibit switching.

Since $\Gamma$ is a global attractor, we may find an open neighbourhood $U$ around $\Gamma$ having its boundary transverse to the flow and such that every solution starting in $U$ remains in it and is forward asymptotic to $\Gamma$. This (small) neighbourhood will be called the absorbing domain of $\Gamma$.

Let $W_1$ and $W_2$ be small disjoint neighbourhoods of $P_1$ and $P_2$ with disjoint boundaries $\partial W_1$ and $\partial W_2$, respectively. Trajectories starting at $\partial W_1$ near $W^s(P_1)$ go into the interior of $W_1$ in positive time, then follow the connection from $P_1$ to $P_2$, go inside $V_2$, and then come out at $\partial W_2$. Let $Q$ be a piece of trajectory like this from $\partial W_1$ to $\partial W_2$. Now join its starting point to its end point by a line segment, forming a closed curve, that we call the loop of $Q$. The loop of $Q$ and $\Gamma$ are disjoint closed sets. Following [22], we say that the two saddle-foci $P_1$ and $P_2$ in $\Gamma$ have the same chirality if the loop of every trajectory is linked to $\Gamma$ in the
sense that the two closed sets cannot be disconnected by an isotopy. From now on, we assume
the following technical condition:

(H5) The equilibria \( P_1 \) and \( P_2 \) have the same chirality.

3.2. Perturbing term. The parameter \( \lambda \) acts on the dynamics of (3.1) in the following way:

(H6) For \( \lambda > 0 \), the two trajectories \( \gamma_1 \) and \( \gamma_2 \) within \( W^u(P_1) \cap W^s(P_2) \) persist.

(H7) For \( \lambda > 0 \), the manifolds \( W^u(P_2) \) and \( W^s(P_1) \) intersect transversely.

and

(H8) There exist \( \varepsilon > 0 \) and \( \lambda_1 > 0 \) for which the global maps associated to the connections
\[[P_1 \rightarrow P_2] \quad \text{and} \quad [P_2 \rightarrow P_1]\]
are given, in local coordinates, by the Identity map and by the expression:
\[
\left( \begin{array}{c} x \\ y \end{array} \right) \mapsto \left( \begin{array}{c} \xi \\ 0 \end{array} \right) + \left( \begin{array}{cc} 1 & 0 \\ 0 & 1 \end{array} \right) \left( \begin{array}{c} x \\ y \end{array} \right) + \lambda \left( \begin{array}{c} \Phi_1(x, y) \\ \Phi_2(x, y) \end{array} \right)
\]
for \( \lambda \in [0, \lambda_1] \) respectively, where \( \xi \in \mathbb{R} \),
\[
\Phi_1 : S^1 \times [-\varepsilon, \varepsilon] \rightarrow \mathbb{R}, \quad \Phi_2 : S^1 \times [-\varepsilon, \varepsilon] \rightarrow \mathbb{R}
\]
are \( C^2 \)-maps and \( \Phi_2(x, 0) \) is a Morse function with two nondegenerate critical points
(at \( \pi/2 \) and \( 3\pi/2 \)) and two zeros (at 0 and \( 2\pi \)). This assumption will be clearer later
in Section 4.

For \( r \geq 3 \), denote by \( \mathcal{X}^r_{Byk}(S^3) \), the family of \( C^r \)-vector fields on \( S^3 \) endowed with the \( C^r \)-Whitney topology, satisfying Properties (H1)–(H8). Note that for \( \lambda > 0 \), the flow of \( g_\lambda \) has a Bykov cycle whose dynamics have been explored in [9, 21, 26], which explains the
subscript \( Byk \) in \( \mathcal{X}^r_{Byk}(S^3) \).

3.3. Constants. We settle the following notation on the saddle-values of \( P_1, P_2 \) and \( \Gamma \):
\[
\delta_1 = \frac{C_1}{E_1} > 1, \quad \delta_2 = \frac{C_2}{E_2} > 1, \quad \delta = \delta_1 \delta_2 > 1 \tag{3.2}
\]
and on the twisting number defined as:
\[
K_\omega = \frac{E_2 \omega_1 + C_1 \omega_2}{E_1 E_2} > 0. \tag{3.3}
\]

The terminology “twisting number” is due to the effect of this number on the dynamics: if it is large enough, then it forces the spread of trajectories around a two-dimensional manifold.

3.4. Main results. Let \( \mathcal{T} \) be a neighborhood of the attractor \( \Gamma \) that exists for \( \lambda = 0 \). For \( \lambda_0 > 0 \) small enough and \( r \geq 3 \), let \( (g_\lambda)_{\lambda \in [0, \lambda_0]} \) be a one-parameter family of vector fields in \( \mathcal{X}^r_{Byk}(S^3) \).
Proposition 3.2. Let $g_{\lambda} \in \mathcal{X}_{Byk}^r(S^3)$, $\lambda \in [0, \lambda_0]$. Then, there is $\varepsilon > 0$ such that the first return map to a given cross section $\Sigma$ to $\Gamma$ may be written \(^1\) by:

$$
G_{\lambda}(x, y) = \left[ x + \xi + \lambda \Phi_1(x, y) - K_\omega \ln |y + \lambda \Phi_2(x, y)| \right] \pmod{2\pi}, \quad (y + \lambda \Phi_2(x, y)) \delta + \ldots
$$

where $\xi \in \mathbb{R}$,

$$(x, y) \in \mathcal{D} = \{ x \in \mathbb{R} \pmod{2\pi}, \quad y/\varepsilon \in [-1, 1] \quad \text{and} \quad y + \lambda \Phi_2(x, y) \neq 0 \} \subset \Sigma$$

and the ellipses stand for asymptotically small terms depending on $x$ and $y$ converging to zero along with their first derivatives.

The proof of Proposition 3.2 is adapted from \([30]\) and will be revisited in Section 5. Since $\delta > 1$, for $\lambda > 0$ small enough, the second component of $G_{\lambda}$ is contracting and its dynamics is dominated by the family of circle maps with singularities:

$$
h_a(x) = x + a + \xi + K_\omega \ln |\Phi_2(x)|
$$

where:

- $x \in \mathbb{S}^1 \equiv \mathbb{R}/(2\pi \mathbb{Z})$;
- $\xi \in \mathbb{R}$;
- $a = -K_\omega \ln \lambda \pmod{2\pi}$, $\lambda \in ]0, \lambda_0]$ and
- $\Phi_2(x) \equiv \Phi_2(x, 0)$ is the map defined in (H8). The singularities are the zeros of $\Phi_2$.

The next result shows that, for any small unfolding of $g_0$, in the $C^3$–Whitney topology, there is a sufficiently large twisting number prompting the persistence of “large” strange attractors (for $G_{\lambda}$ defined in Proposition 3.2).

Theorem A. Let $(g_{\lambda})_{\lambda} \in \mathcal{X}_{Byk}^r(S^3)$ with $r \geq 3$. For $K_\omega^0 > 0$ large enough, there exists a set $\Delta_{\lambda} \subset [0, \lambda_0]$ with positive Lebesgue measure such that if $\lambda \in \Delta_{\lambda}$, then the flow of $g_{\lambda}$ contains a “large” strange attractor.

If $\lambda \in \Delta_{\lambda}$, the non-wandering dynamics of $g_{\lambda}$ is governed by the two-dimensional set $W^u(P_2)$. The proof of Theorem A is performed in Section 9 by reducing the dynamics of the two-dimensional first return map to the dynamics of a one-dimensional map. Since $\Phi_2$ has zeros, the singular limit (called $h_a$ in (7.1)) is not defined in a compact set and has singularities with unbounded derivatives near them. The classical theory of Rank-one strange attractors developed by Wang and Young \([32]\) cannot be applied directly to the case under consideration.

For $\lambda > 0$, the network $\Gamma$ is broken and a more complex network $\Gamma_{\lambda}$ emerges as a consequence of (H6) and (H7). This network consists of the two connections of (H6) and infinitely many connections resulting from $W^u(P_2) \cap W^s(P_1)$ (Proposition 3.2 of \([21]\)). The authors of \([21]\) proved that there is infinite switching near $\Gamma_{\lambda}$. In this paper, we go further by proving the existence of abundant infinite switching. This is the content of the next result:

\(^6\)In the local coordinates $(x, y)$ of the cross-section $\Sigma$ defined in Section 4.
Theorem B. Let \((g_\lambda) \in X^r_{Byk}(S^3)\) with \(r \geq 3\). For \(K_0^c > 0\) large enough, there exists a set \(\Delta_\lambda \subset [0, \lambda_0] \) with positive Lebesgue measure such that if \(\lambda \in \Delta_\lambda\), then the network \(\Gamma_\lambda\) exhibits abundant infinite switching. This phenomenon is realized by any non-empty ball of initial conditions lying in \(\mathcal{U}\).

Theorem B may be seen as a consequence of Theorem A and its proof is done in Section 10.

3.5. Digestive remarks. In this subsection, we point out some remarks about the Hypotheses (H1)–(H8) and the main results.

Remark 3.3. The “large” strange attractors of Theorem A contain non-uniformly hyperbolic horseshoes. The horseshoes whose existence has been proven in \([21, 23, 26]\) are uniformly hyperbolic but they do not correspond to the whole non-wandering set associated to \(\mathcal{U}\); they are restricted to a small “window” near \(\Gamma_\lambda, \lambda > 0\).

Remark 3.4. The full description of the bifurcations associated to \(\Gamma\) is a phenomenon of codimension three. Nevertheless, the setting described by (H1)–(H8) is natural in \(\mathbb{SO}(2)–\)symmetry-breaking contexts \([21, 27]\) and also in the scope of some unfoldings of the Hopf-zero singularity \([6]\).

Remark 3.5. Hypothesis (H6) corresponds to the partial symmetry-breaking considered in Section 2.4 of \([21]\). The setting described by (H1)–(H8) generalizes Cases (2) and (3) of \([29]\). Hypothesis (H8) is generic if we consider one of the simplest scenarios for the splitting of the sphere defined by the coincidence of the two-dimensional invariant manifolds.

Remark 3.6. For \(\lambda > 0\), the flow of \(g_\lambda\) exhibits a heteroclinic tangle. The distance between \(W^u_{loc}(P_2)\) and \(W^s_{loc}(P_1)\) in a cylindrical cross-section to \(\Gamma\) may be computed using the Melnikov integral \([27, \text{Appendix A}]\); the map \(\Phi_2(x)\) may be seen as the Melnikov integral, up to a possible reparametrisation. The proofs of Theorems A and B are analogous if \(\Phi_2(x,0)\) is a Morse function with a finite number of nondegenerate critical points and a finite number of zeros.

Remark 3.7. The analytical expressions for the transitions maps along the heteroclinic connections \([P_1 \to P_2]\) and \([P_2 \to P_1]\) could be written as a general Linear map as:

\[
\begin{pmatrix}
  x \\
  y
\end{pmatrix} \mapsto \begin{pmatrix}
  a & 0 \\
  0 & \frac{1}{a}
\end{pmatrix} \begin{pmatrix}
  x \\
  y
\end{pmatrix},
\]

and by

\[
\begin{pmatrix}
  x \\
  y
\end{pmatrix} \mapsto \begin{pmatrix}
  \xi_1 \\
  \xi_2
\end{pmatrix} + \begin{pmatrix}
  b_1 & b_2 \\
  c_1 & c_2
\end{pmatrix} \begin{pmatrix}
  x \\
  y
\end{pmatrix} + \lambda \begin{pmatrix}
  \Phi_1(x, y) \\
  \Phi_2(x, y)
\end{pmatrix},
\]

respectively, where \(a \geq 1, \xi_1, \xi_2, b_1, b_2, c_1, c_2 \in \mathbb{R}\). For the sake of simplicity, we restrict to the case \(a = b_1 = c_2 = 1\) and \(\xi_1 = \xi_2 = b_2 = c_1 = 0\). This simplifies the computations and is not a restriction \([26, \S 6]\).

4. Local and transition maps

In this section we will analyze the dynamics near the network \(\Gamma_\lambda, \lambda > 0\) through local maps, after selecting suitable coordinates in the neighbourhoods of the saddle-foci \(P_1\) and \(P_2\). Note that \(\Gamma_0 \equiv \Gamma\).
4.1. **Local coordinates.** We use the local coordinates near the equilibria $P_1$ and $P_2$ introduced in [23].

We consider cylindrical neighbourhoods $W_1$ and $W_2$ in $\mathbb{R}^3$ of $P_1$ and $P_2$, respectively, of radius $\rho = \varepsilon > 0$ and height $z = 2\varepsilon$. After a linear rescaling of the variables, we assume that $\varepsilon = 1$. Their boundaries consist of three components: the cylinder wall parametrised by $x \in \mathbb{R}$ (mod $2\pi$) and $|y| \leq 1$ with the usual cover

$$(x, y) \mapsto (1, x, y) = \left(\rho, \theta, z\right),$$

and two discs, the top and bottom of the cylinder. We take polar coverings of these disks

$$(r, \varphi) \mapsto (r, \varphi, \pm 1) = \left(\rho, \theta, z\right),$$

where $0 \leq r \leq 1$ and $\varphi \in \mathbb{R}$ (mod $2\pi$). The local stable manifold of $P_1$, $W^s(P_1)$, corresponds to the circle parametrised by $y = 0$. In $W_1$ we use the following terminology:

- **In$(P_1)$**, the cylinder wall of $W_1$, consisting of points that go inside $W_1$ in positive time;
- **Out$(P_1)$**, the top and bottom of $W_1$, consisting of points that go outside $W_1$ in positive time. It has two connected components.

We denote by In$^+(P_1)$ the upper part of the cylinder, parametrised by $(x, y)$, $y \in ]0, 1[$ and by In$^-(P_1)$ its lower part.

The cross-sections obtained for the linearisation of $g_\lambda$ around $P_2$ are dual to these. The set $W^u(P_2)$ is the $z$-axis intersecting the top and bottom of the cylinder $W_2$ at the origin of its coordinates. The set $W^u(P_2)$ is parametrised by $z = 0$, and we use:

- **In$(P_2)$**, the top and bottom of $W_2$, consisting of points that go inside $W_2$ in positive time;
- **Out$(P_2)$**, the cylinder wall of $W_2$, consisting of points that go inside $W_2$ in negative time, with Out$^+(P_2)$ denoting its upper part, parametrised by $(x, y)$, $y \in ]0, 1[$ and Out$^-(P_2)$ its lower part parametrised by $(x, y)$, $y \in ]-1, 0[$.

We will denote by $W^u_{\text{loc}}(P_2)$ the portion of $W^u(P_2)$ that goes from $P_2$ to In$(P_1)$ not intersecting the interior of $W_1$ and by $W^s_{\text{loc}}(P_1)$ the portion of $W^s(P_1)$ outside $W_2$ that goes directly from Out$(P_2)$ into $P_1$. The flow is transverse to these cross-sections and the boundaries of $W_1$ and of $W_2$ may be written as In$(P_1) \cup$ Out$(P_1)$ and In$(P_2) \cup$ Out$(P_2)$. The orientation of the angular coordinate near $P_2$ is chosen to be compatible with the direction induced by Hypotheses (H4) and (H5).

4.2. **Local maps near the saddle-foci.** Following Proposition 3.1 of [13], the trajectory of a point $(x, y)$ with $y > 0$ in In$^+(P_1)$ leaves $W_1$ at Out$(P_1)$ at

$$L_1(x, y) = \left(y^{\delta_1} + S_1(x, y; \lambda), \frac{\omega_1 \ln y}{E_1} + x + S_2(x, y; \lambda)\right) = (r, \varphi),$$

(4.1)
where \( S_1 \) and \( S_2 \) are smooth functions which depend on \( \lambda \) and satisfy:

\[
\left| \frac{\partial^{k+l+m}}{\partial x^k \partial y^l \partial \lambda^m} S_i(x, y; \lambda) \right| \leq C y^{\delta_1 + \sigma - l},
\]

and \( C \) and \( \sigma \) are positive constants and \( k, l, m \) are non-negative integers. Similarly, a point \((r, \varphi)\) in \( \text{In}(P_2) \setminus \text{Ws}_{\text{loc}}(P_2)\), leaves \( W_2 \) at \( \text{Out}(P_2) \) at

\[
L_2(r, \varphi) = \left(-\frac{\omega_2 \ln r}{E_2} + \varphi + R_1(r, \varphi; \lambda), r^{\delta_2} + R_2(r, \varphi; \lambda)\right) = (x, y)
\]

where \( R_1 \) and \( R_2 \) satisfy a condition similar to (4.2). The terms \( S_1, S_2, R_1, R_2 \) correspond to asymptotically small terms that vanish when the components \( y \) and \( r \) go to zero.

### 4.3. The transitions.

The coordinates on \( W_1 \) and \( W_2 \) are chosen so that \([P_1 \to P_2]\) connects points with \( z > 0 \) (resp. \( z < 0 \)) in \( W_1 \) to points with \( z > 0 \) (resp. \( z < 0 \)) in \( W_2 \). Points in \( \text{Out}(P_1) \) near \( W^u(P_1) \) are mapped into \( \text{In}(P_2) \) along a flow-box around each of the connections \([P_1 \to P_2]\). We will assume that the transitions \( \Psi_{1 \to 2}^+: \text{Out}^+(P_1) \to \text{In}^+(P_2) \) \( \Psi_{1 \to 2}^-: \text{Out}^-(P_1) \to \text{In}^-(P_2) \) do not depend on \( \lambda \) and may be considered as the Identity map, as a consequence of Hypothesis (H4) and (H8). Denote by \( \eta^+, \eta^- \) the following maps:

\[
\eta^+ = L_2 \circ \Psi_{1 \to 2}^+ \circ L_1: \quad \text{In}^+(P_1) \to \text{Out}^+(P_2)
\]

\[
\eta^- = L_2 \circ \Psi_{1 \to 2}^- \circ L_1: \quad \text{In}^-(P_1) \to \text{Out}^-(P_2).
\]

From (4.1) and (4.3), omitting high order terms in \( y \) and \( r \), we conclude that, in local coordinates of \( \text{In}(P_1) \setminus \text{Ws}_{\text{loc}}(P_1) \) (\( \iff |y| \neq 0 \)), we have:

\[
\eta(x, y) = \left(x - K_\omega \log |y| \pmod{2\pi}, y^\delta\right)
\]

with

\[
\delta = \delta_1 \delta_2 > 1 \quad \text{and} \quad K_\omega = \frac{C_1 \omega_2 + E_2 \omega_1}{E_1 E_2} > 0.
\]

Using (H7) and (H8), for \( \lambda \in [0, \lambda_1] \), we have a well defined transition map \( \Psi_{2 \to 1}^\lambda: \text{Out}(P_2) \to \text{In}(P_1) \) that depends on the parameter \( \lambda \), given by:

\[
\Psi_{2 \to 1}^\lambda(x, y) = (\xi + x + \lambda \Phi_1(x, y), y + \lambda \Phi_2(x, y))
\]

To simplify the notation, in what follows we will sometimes drop the superscript \( \lambda \), unless there is some risk of misunderstanding. By (H8), the map \( \ln \Phi_2(x, 0) \) has two singularities and two critical points – see Figure 1.
In(P ) \[ 0 \] \[ 2\pi \]
Out(P ) \[ 2 \]
\[ 0 \]
\[ 2\pi \]
W u(P ) \[ 2 \]
W s(P ) \[ 1 \]
\[ \psi \]
\[ \Phi (x,0) \]
\[ \lambda \]
\[ \Gamma \]
\[ \sigma \]
\[ \delta \]

Figure 1. Illustration of the transition map \( \psi^\lambda_{2 \to 1} \) from Out(P ) to In(P ). The graph of \( \Phi_2(x,0) \equiv \Phi_2(x) \) may be seen as the first hit of \( W^u_{loc}(P_2) \) to In(P ).

5. Proof of Proposition 3.2

The proof of Proposition 3.2 is straightforward by considering \( \Sigma = \text{Out}(P_2) \) and by composing the local and global maps constructed in Section 4. More specifically, let

\[ G_\lambda = \eta \circ \psi_{2 \to 1} : \mathcal{D} \subset \text{Out}(P_2) \setminus W^s_{loc}(P_1) \to \mathcal{D} \subset \text{Out}(P_2) \]

be the first return map to \( \mathcal{D} \), where \( \mathcal{D} \subset \text{Out}(P_2) \) is the set of initial conditions \((x,y) \in \text{Out}(P_2)\) whose solution returns to \( \text{Out}(P_2) \). Up to high order terms, composing (4.4) with (4.6), the analytic expression of \( G_\lambda \) is given by:

\[ G_\lambda(x,y) = \begin{bmatrix} x + \xi + \lambda \Phi_1(x,y) - K_\omega \ln |y + \lambda \Phi_2(x,y)| \pmod{2\pi}, \ (y + \lambda \Phi_2(x,y))^\delta \\ \end{bmatrix} \]

Initial conditions \((x,y)\) that do not return to \( \text{Out}(P_2) \) are contained in \( W^s(P_1) \); such points are parametrized by \( y + \lambda \Phi_2(x,y) = 0 \). Although the map is \( C^\infty \) (where it is well defined), the approximation of \( G_\lambda \) may be performed in a \( C^2 \)-topology since the local maps \( L_1 \) and \( L_2 \) may be taken to be \( C^{r-1} \) and the global maps are assumed to be \( C^2 \)-embeddings.

Remark 5.1. When \( \lambda = 0 \), we may write (for \(|y| \neq 0\)):

\[ G_0(x,y) = \begin{bmatrix} \xi + x - K_\omega \ln |y| \pmod{2\pi}, \ y^\delta \end{bmatrix} \]

This means that the \( y \)-component is contracting and thus the dynamics is governed by the \( x \)-component. This is consistent with the fact that \( \Gamma \) is attracting (Lemma 5.1). If \( y = 0 \) and \( x \in \mathbb{S}^1 \), then \((x,y) \in W^s(P_1)\), implying that the associated trajectory does not return to \( \Sigma \).

6. Singular limit

In this section, we compute the singular limit set associated to \( G_\lambda \) defined in Proposition 3.2. The formal definition of singular limit may be found in [30, 32].

\[ \text{Notice that } r \geq 3 \text{ is the class of differentiability of the initial vector field} \]
6.1. **Change of coordinates.** For $\lambda \in ]0, \lambda_1[$ fixed and $(x, y) \in \text{Out}(P_2)$, let us make the following change of coordinates:

$$\bar{x} \mapsto x \quad \text{and} \quad \bar{y} \mapsto \frac{y}{\lambda} (\Leftrightarrow y = \bar{y} \lambda). \quad (6.1)$$

Taking into account that:

$$G_1^{\lambda}(x, y) = x + \xi + \lambda \Phi_1(x, y) - K_\omega \ln |y + \lambda \Phi_2(x, y)| \quad (\text{mod } 2\pi)$$

$$G_2^{\lambda}(x, y) = (y + \lambda \Phi_2(x, y)) \delta = \lambda \delta \left(\frac{y}{\lambda} + \Phi_2(x, y)\right),$$

we may write:

$$G_1^{\lambda}(x, \lambda \bar{y}) = x + \xi + \lambda \Phi_1(x, \lambda \bar{y}) - K_\omega \ln \lambda - K_\omega \ln |\bar{y} + \Phi_2(x, \lambda \bar{y})| \quad (\text{mod } 2\pi)$$

$$G_2^{\lambda}(x, \lambda \bar{y}) = \lambda^{\delta - 1} (\bar{y} + \Phi_2(x, \lambda \bar{y})) \delta.$$

6.2. **Reduction to a singular limit.** In this subsection, we compute the singular limit of $G_\lambda$ written in the coordinates $(x, \bar{y})$ and studied in Subsection 6.1, for $\lambda \in ]0, \lambda_1[$. Let $k : \mathbb{R}^+ \to \mathbb{R}$ be the invertible map defined by

$$k(x) = -K_\omega \ln(x),$$

whose graph is depicted in Figure 2. Define now the decreasing sequence $(\lambda_n)_n$ such that, for all $n \in \mathbb{N}$, we have:

1. $\lambda_n \in ]0, \lambda_1[$ (the meaning of $\lambda_1$ comes from \text{(H8)}) and
2. $k(\lambda_n) \equiv 0 \pmod{2\pi}$.

Since $k$ is invertible, for $a \in S^1 \equiv [0, 2\pi]$ fixed and $n \geq n_0 \in \mathbb{N}$, let

$$\lambda_{(a,n)} = k^{-1} [k(\lambda_n) + a] \in ]0, \lambda_1[,$$

as shown in Figure 2. We may write:

$$k \left(\lambda_{(a,n)}\right) = -K_\omega \ln(\lambda_n) + a = a \quad (\text{mod } 2\pi). \quad (6.3)$$

The following proposition establishes the convergence of the map $G_{\lambda_{(a,n)}}$ to a singular limit as $n \to +\infty$, ($\| \cdot \|_{C^r}$ represents the norm in the $C^r$–topology for $r \geq 2$):

**Lemma 6.1.** The following equality holds:

$$\lim_{n \in \mathbb{N}} \|G_{\lambda_{(a,n)}}(x, \bar{y}) - (h_a(x, \bar{y}), 0)\|_{C^a} = 0$$

where $0$ is the null map and

$$h_a(x, \bar{y}) = x + a - K_\omega \ln |\bar{y} + \Phi_2(x, \bar{y})| + \xi. \quad (6.4)$$
Proof. Using (6.3), we have

\[
G_1^{\lambda(n,a)}(x, y) = x + \xi + \lambda(n,a)\Phi_1(x, y) - K_\omega \ln \lambda(n,a) - K_\omega \ln |y + \Phi_2(x, y)| \quad \text{(mod 2\pi)}
\]

\[
= x + \xi + \lambda(n,a)\Phi_1(x, y) + a - K_\omega \ln |(y + \Phi_2(x, y))| \quad \text{(mod 2\pi)}
\]

\[
G_2^{\lambda(n,a)}(x, y) = \lambda(n,a)^{\delta-1} (y + \Phi_2(x, y))^\delta.
\]

Since \( \lim_{n \to \infty} \lambda(n,a) = 0 \) we may write:

\[
\lim_{n \to \infty} G_1^{\lambda(n,a)}(x, y) = x + \xi + a - K_\omega \ln |\Phi_2(x, 0)| \quad \text{(mod 2\pi)}
\]

\[
\lim_{n \to \infty} G_2^{\lambda(n,a)}(x, y) = 0
\]

and we get the result. \(\square\)

Assuming that \( \Phi_2(x, 0) \equiv \Phi_2(x) \), the map

\[
h_a(x) = x + \xi + a - K_\omega \ln |\Phi_2(x)|
\]

is the singular limit in the spirit of [32]; it has two nondegenerate critical points and two singularities – see Figure 3. The map \( h_a \) is not defined on a compact set and its derivative explodes to \( \infty \) near the singularities. Since \( h_a \) is not a Misiurewicz-type map in the sense of...
the Theory of Rank-one attractors cannot be applied to this case and results should be adapted.

Figure 3. Graph of $|\Phi_2(x)|$ (upper image) and $h_\sigma(x) = x + \xi + a - K_\omega \ln |\Phi_2(x)|$ (lower image). For $\sigma > 0$, the sets $C_\sigma$ and $S_\sigma$ represent neighbourhoods of the critical and singular set of $h_\sigma$.

7. Related results

To make a coherent presentation, in this section we collect the ideas from [31] that will be used in the sequel. We hope this saves the reader the trouble of going thought the entire length of [31]. From now on, we locate the singular and critical sets of

$$h_\sigma(x) = x + \xi + a - K_\omega \ln |\Phi_2(x)|$$

(7.1)
where $x \in S^1 \setminus \{0, \pi\}$. These sets are endowed with the distance $\text{dist}$ (euclidean distance on $S^1 \equiv \mathbb{R}/(2\pi \mathbb{Z})$):

$$S = \{ x \in S^1 : \Phi_2(x) = 0 \} = \{ 0, \pi \} \mapsto \text{Singular set}$$

$$C = \{ x \in S^1 : \Phi'_2(x) = 0 \} = \left\{ \frac{\pi}{2}, \frac{3\pi}{2} \right\} \mapsto \text{Critical set}$$

and, for $\sigma > 0$, define (see red and green bold lines in Figure 3):

$$S_{\sigma} = \{ x \in S^1 : \text{dist}(x, S) \leq \sigma \} \quad \text{and} \quad C_{\sigma} = \{ x \in S^1 : \text{dist}(x, C) \leq \sigma \}.$$

Since

$$h'_a(x) = 1 - K\omega \frac{\Phi'_2(x)}{\Phi_2(x)} \quad \text{and} \quad h''_a(x) = K\omega \frac{\Phi''_2(x)\Phi_2(x) - (\Phi'_2(x))^2}{(\Phi'_2(x))^2},$$

it follows:

**Lemma 7.1** (Lemma 2.1 of [31], adapted). There exist $K_0 > 1$ and $\varepsilon > 0$ such that the following inequalities hold for $K_\omega$ sufficiently large:

(1) for all $x \in S^1 \setminus \{0, \pi\}$, we have

$$\frac{K_\omega \text{dist}(x, C)}{K_0 \text{dist}(x, S)} \leq |h'_a(x)| \leq K_\omega K_0 \frac{\text{dist}(x, C)}{\text{dist}(x, S)};$$

(2) if $x \in S^1$, we have:

$$|h'_a(x)| \geq \frac{K_\omega}{K_0} \varepsilon \quad \text{if} \quad x \notin C_\varepsilon$$

$$\frac{K_\omega}{K_0} < |h''_a(x)| < K_\omega K_0 \quad \text{if} \quad x \in C_\varepsilon.$$

Item (1) of Lemma 7.1 says that the derivative of $h_a$ at $x \in S^1 \setminus \{0, \pi\}$ goes like the inverse of the distance of $x$ to the singular set $S$: if $x$ approaches $S$, then $h'_a(x)$ explodes. This does happen for Misiurewicz-type maps (see §5 of [30]). Now, we define an interval around the critical point $c \in C$ which “generates” a strange attractor. In order to do that, we need to introduce some terminology from [31].
\[ c \mapsto \text{critical point of (7.1)} \]

\[ c_n = h_a^{n+1}(c), \quad n \in \mathbb{N}_0 \]

\[ \xi(n) = \frac{1}{(K_\omega)^{n/10^3}} > 0, \quad n \in \mathbb{N}_0 \]

\[ J(x) = |h_a'(x)| \]

\[ J^n(x) = J(x).J(h_a(x)).J(h_a^2(x))...J(h_a^{n-1}(x)) \]

\[ d_n(c_0) = \frac{\text{dist}(c_n, C), \text{dist}(c_n, S)}{J^n(c_0)}, \quad n \in \mathbb{N} \]

\[ D_n(c_0) = \frac{1}{\sqrt{K_\omega}} \left[ \sum_{i=0}^{n-1} \frac{1}{d_i(c_0)} \right]^{-1} \]

\[ (n \geq 2) \quad I_n(c) = \begin{cases} 
  h_a^{-1}[c_0 + D_{n-1}(c_0), c_0 + D_n(c_0)], & \text{if } c \text{ is a minimum of (7.1)} \\
  h_a^{-1}[c_0 - D_{n}(c_0), c_0 - D_{n-1}(c_0)], & \text{if } c \text{ is a maximum of (7.1)}
\end{cases} \]

For \( c \in C, \xi = \xi(n) > 0 \) and \( n \in \mathbb{N} \), denote also the following sets:

\[ \Delta_n = \{ a \in S^1 : (h_a^{i+1}(C)) \cap (C_\xi \cup S_\xi) = \emptyset, \quad \text{for all } i \in \{1, ..., n\} \} \]

\[ \Delta = \left\{ a \in S^1 : |h_a^n(h_a(c))| \geq (K_\omega)^{\frac{n}{10^3}}, \quad \text{for all } n \in \mathbb{N} \right\}. \]

**Interpretation.** In what follows we give an interpretation of the previous constants, sets and intervals:

- The set \( I_n(c) \) is the union of two small intervals containing \( c \in C \) in one of their borders, whose amplitude tends to 0 as \( K_\omega \) goes to \(+\infty\).

- For all \( n \in \mathbb{N} \) and \( c \in C \), we have \( D_{n-1}(h_a(c)) < D_n(h_a(c)) \).

- If \( x \in I_n(c) \), then \( |h_a(x) - h_a(c)| \leq D_{n-1}(h_a(c)) \). The derivatives along the orbit of \( h_a(x) \) shadow that of the orbit of \( h_a(c) \) for \( n-1 \) iterates.

- If \( a \in \Delta \), then for all \( n \in \mathbb{N} \), \( J^n(c) \neq 0, d_n(c_0) > 0 \) and \( D_n(c_0) > 0 \).

- The set \( \Delta \) depends on \( K_\omega \).
Lemma 7.2 (31, adapted). The following assertions hold:

1. For any arbitrarily large $N \in \mathbb{N}$, we have: $\text{Leb}_1(\Delta_N) \geq 2\pi - \frac{1}{(K_\omega)^\frac{1}{9}}$.

2. There exists $K_\omega^* \gg 1$ such that for $K_\omega > K_\omega^*$ then:
   $$|\langle h_a^n \rangle(h_a(c))| \geq (K_\omega)^{n/1000}$$
   for all $n \in \mathbb{N}$, $a \in \Delta$ and $c \in \mathcal{C}$.

Item (2) of Lemma 7.2 means that there exists an exponential growth of the derivative along the orbit of the critical point $c \in \mathcal{C}$. Using (1) of Lemma 7.2 we may conclude that:

$$\lim_{K_\omega \to +\infty} \text{Leb}_1(\Delta) = 2\pi.$$ Indeed,

$$2\pi \geq \text{Leb}_1(\Delta) \geq \text{Leb}_1(\Delta_N) - \sum_{n=N+1}^{\infty} \text{Leb}_1(\Delta_{n-1}\setminus\Delta_n) \geq 2\pi - (K_\omega)^{-\frac{1}{9}} - \sum_{n=N+1}^{\infty} (K_\omega)^{-\frac{n}{10^7}} - (K_\omega)^{-\frac{n}{3 \cdot 10^6}}.$$ Since

$$\lim_{K_\omega \to +\infty} \left[ 2\pi - (K_\omega)^{-\frac{1}{9}} \right] - \lim_{K_\omega \to +\infty} \left[ \sum_{n=N+1}^{\infty} (K_\omega)^{-\frac{n}{10^7}} - (K_\omega)^{-\frac{n}{3 \cdot 10^6}} \right] = 2\pi,$$

then

$$\lim_{K_\omega \to +\infty} \text{Leb}_1(\Delta) = 2\pi.$$

The next result ensures an exponential growth of derivatives outside $\mathcal{C}_\xi$. Expansion is lost due to returns to this set.

Lemma 7.3 (Lemma 2.5 of 31, adapted). For every $p \geq 2$, $N$ sufficiently large and independent of $K_\omega$, $a \in \Delta_N$ and $x \in I^p(c)$, the following conditions are valid:

1. for $n \geq 1$ such that $x, h_a(x), h_a^2(x), \ldots, h_a^{n-1}(x) \notin \mathcal{C}_\xi$, then $J^n(x) \geq \xi(K_\omega)^\frac{2n}{1000}$;

2. if $x \in \mathcal{C}_\xi$, then $J^n(x) \geq (K_\omega)^\frac{2n}{1000000}$.\footnote{This value of $N$ is independent of $K_\omega$.}

Note that $\xi = \xi(n)$ is defined for $n > N$, where $N$ is large (Item (1) of Lemma 7.2).

Although the next lemma has not been explicitly stated in 31, it is implicit from the combination of Properties (G1)$_{n,c}$ and (G2)$_{n,c}$ on page 537 31. See also the proof of Sublemma 2.4 of 31.

Lemma 7.4 (31, adapted). For sufficiently large $K_\omega$, $a \in \Delta_N$, $N$ sufficiently large and independent of $K_\omega$ and $N_1 \in \{1, \ldots, N\}$, the following conditions hold:

\footnote{From (G1)$_{n,c}$, using the notation of 31, if $i = 0$, we get $J^i(c_0) \geq L \cdot \sigma = L^{5/6}$.}
(1) there exists $k_1 > 0$ such that for all $i < N_1$ we have $\text{dist}(c_i, C), \text{dist}(c_i, S) > k_1$;

(2) $J^{N_1}(c_0) \geq \left( \frac{(k_\omega)^{N_1-N_i}}{k_\theta} \right) J^i(c_0)$, where $i \leq N_1$.

The main results of [31] concludes about the existence of a strange attractor for $h_a$ “generated” by the critical point (see Item (2) of Lemma 7.2). The breakthrough of the present article is to prove that this strange attractor is “large”. This is why we need to refine and extend their results, which is the goal of next section.

**Figure 4.** Graph of $h_a \pmod{2\pi}$ and illustration of the sequences $(c_n)_n$ and $(d_n)_n$ of Lemma 8.1.
8. Effects of the unbounded derivative

The goal of this section is to refine the results of Section 7 adapted to \( h_a \). The following lemma says that there are small intervals near \( s \in \mathcal{S} \) where the image of \( h_a \) covers the whole circle \( S^1 \). Elements of \( \mathcal{S} \) blow up the derivatives of \( h_a \), allowing expansion and enforcing shift dynamics (\( \Leftrightarrow \) chaos).

**Lemma 8.1.** For \( s \in \mathcal{S} \) and \( a \in S^1 \), there exists a nested sequence of intervals of the type \( (c_n, d_n) \in [0, 2\pi] \) such that \( h_a \) is injective in \( (c_n, c_{n+1}) \) and \( (d_n, d_{n+1}) \) and

\[
h_a([c_n, c_{n+1}]) = h_a([d_{n+1}, d_n]) = S^1.
\]

**Proof.** We suggest the reader to follow the proof by observing Figure 4. For \( s = \pi \) (if \( s = 0 \), the proof is similar) and \( a \in S^1 \), since

\[
\lim_{x \to s^+} |\Phi_2(x)| = \lim_{x \to s^-} |\Phi_2(x)| = 0
\]

it follows that

\[
\lim_{x \to s^+} h_a(x) = \lim_{x \to s^-} h_a(x) = +\infty.
\]

As depicted in Figure 4, define the intervals \( \mathcal{I}^- \) and \( \mathcal{I}^+ \) subintervals of \([\pi/2, \pi[ \) and \( ]\pi, 3\pi/2[ \), where \( |\Phi_2| \) is monotonically increasing and decreasing, respectively. They exist because the equation \( h_a'(x) = 0 \) has a unique solution. Indeed,

\[
h_a'(x) = 0 \iff 1 - K \frac{\Phi_2'(x)}{\Phi_2(x)} = 0
\]

\[
\iff K \frac{\Phi_2'(x)}{\Phi_2(x)} = 1.
\]

Define the sequences \( c_n < \pi < d_n \) as:

- \( h_a(c_n) = h_a(d_n) = 2n\pi, \quad n \in \mathbb{N} \)
- for all \( n \in \mathbb{N} \), \( c_n \in \mathcal{I}^- \) and \( d_n \in \mathcal{I}^+ \).

Now it is easy to check that

\[
h_a([c_n, c_{n+1}]) = h_a([d_{n+1}, d_n]) = [0, 2\pi] \equiv S^1.
\]

**Lemma 8.2.** Let \( a \in \Delta \) and let \( \varepsilon > 0 \) be arbitrarily small. For any non-degenetate interval \( I \subset [0, 2\pi[ \setminus \mathcal{S} \) of length \( \varepsilon > 0 \), there exists a subinterval \( I_1 \subset I \) and \( N_1 \in \mathbb{N} \) such that \( h_a^{N_1}(I_1) \) coincides with one of the components of \( C_\varepsilon \cup \mathcal{S}_\varepsilon \).

**Proof.** Let us fix \( \varepsilon > 0 \) and let \( N \) sufficiently large in such a way that \( \xi = \xi(N) < \varepsilon \). Let us iterate by \( h_a \) the interval \( I_1 \), deleting all parts that fall into \( C_\xi \cup \mathcal{S}_\xi \). Suppose that this may be continued up to step \( n \in \mathbb{N} \).

---

\(^{10}\)Defined in Section 4
Under the conditions of Lemma 7.3, the dynamics of $h_\alpha$ is uniformly expanding outside the set $C_\xi$. Therefore, the number of deleted segments at step $i \leq n$ is $\leq 2$. The Lebesgue measure of the deleted parts in $I$ is less or equal than $4\xi \left(1 + (K_\omega)^{-2.10^{-3}} + (K_\omega)^{-2.2.10^{-3}} + \ldots + (K_\omega)^{-2.n10^{-3}}\right)$, and the Lebesgue measure of the undeleted segment in $h_\alpha^n(I)$ is greater or equal than $(\varepsilon - 4\xi \left(1 + (K_\omega)^{-2.10^{-3}} + (K_\omega)^{-2.2.10^{-3}} + \ldots + (K_\omega)^{-2.n10^{-3}}\right)).\xi \left(K_\omega\right)^{2.n.10^{-3}}$, which is greater than $2\pi$ after a finite number of iterates, say $N_1^\ast$. The interval $I_1$ is one of the connected components of the pre-image of $C_\xi \cup S_\xi$ under the map $h_\alpha^{N_1^\ast}(I)$. This proves the lemma.

The previous result says that after a finite number of iterates of $h_\alpha$, any (non-degenerate) interval covers one of the components of $C_\xi \cup S_\xi$. Therefore, we have two disjoint cases:

**Case A:** $h_\alpha^{N_1^\ast}(I_1)$ intersects $S_\xi$. By Lemma 8.1, the interval $I_1$ is sent by $h_\alpha^{N_1^\ast+1}(I_1)$ into the whole $S^1$.

**Case B:** $h_\alpha^{N_1^\ast}(I_1)$ intersects $C_\xi$. Therefore part of the interval follows the orbit of the critical point and $h_\alpha^{N_1^\ast}(I_1) \supset I_{N_1}(c)$ for some $N_1 \in \mathbb{N}$.

For the sake of completeness, we present the following elementary result that will be used in the sequel.

**Lemma 8.3.** For $a > 1$ and $N_1 \in \mathbb{N}$, the following equality holds:

$$
\sum_{i=1}^{N_1} \frac{1}{a^i} = \frac{a^{N_1} - 1}{a^{N_1}(a - 1)} < \frac{1}{a - 1}.
$$

**Proof.** The proof of this result is quite elementary taking into account the formula for the sum of $N_1$ terms of a geometric sum. For the sake of completeness, we present the proof without deep details:

$$
\sum_{i=1}^{N_1} \frac{1}{a^i} = \frac{1}{a} \left(\frac{1 - \frac{1}{a^{N_1}}}{1 - \frac{1}{a}}\right) = \frac{a^{N_1} - 1}{a^{N_1}(a - 1)} < \frac{a^{N_1}}{a^{N_1}(a - 1)} = \frac{1}{a - 1}.
$$

The following lemma says that after a finite number of iterations of $h_\alpha$, the set $h_\alpha^{N_1^\ast}(I_1)$ covers the whole circle $S^1$. It concludes the series of results extending the approximations of Section 7. In its statement, we claim the existence of positive real numbers $k_2, k_3$ and $k_4$ without their explicit expression. However, they are clear if we go deeper into the proof.
Lemma 8.4. Under the terminology of Section 7, the following inequalities hold for $N_1 \in \mathbb{N}$:

1. There exists $k_2 > 0$ such that
   \[ \sum_{i=0}^{N_1-1} \frac{J^i(c_0)}{\text{dist}(c_i, C) \text{dist}(c_i, S)} \leq \frac{k_2^2}{(K_\omega)^{5/6} - 1} \]

2. There exists $k_3 > 0$ such that
   \[ J^{N_1}(c_0) D_{N_1}(c_0) > k_3 (K_\omega)^{1/3} \]

3. If $K_\omega$ is large enough, then $h^{N_1+1}(I_{N_1}(c)) = S^1$.

Proof. The proof follows from the previous results. We proceed to explain with detail all the steps.

(1)
\[
\sum_{i=0}^{N_1-1} \frac{J^i(c_0)}{\text{dist}(c_i, C) \text{dist}(c_i, S)} \leq \sum_{i=0}^{N_1-1} \frac{J^{N_1}(c_0)(K_\omega)^{5(i-N_1)/6} K^*}{k_1^2} \quad \text{where } K^* > 0
\]
\[
\leq \frac{J^{N_1}(c_0)K^*}{k_1^2} \sum_{i=0}^{N_1-1} \frac{1}{(K_\omega)^{5(i-N_1)/6}}
\]
\[
\leq \frac{J^{N_1}(c_0)K^*}{k_2^2} \frac{1}{(K_\omega)^{5/6} - 1}
\]
\[
= \frac{k_2}{(K_\omega)^{5/6} - 1} \quad \text{where } k_2 = \frac{J^{N_1}(c_0)K^*}{k_1^2} > 0.
\]

(2)
\[
J^{N_1}(c_0) D_{N_1}(c_0) = \frac{J^{N_1}(c_0)}{\sqrt{K_\omega}} \left[ \sum_{i=0}^{N_1-1} \frac{1}{d_i(c_0)} \right]^{-1}
\]
\[
= \frac{J^{N_1}(c_0)}{\sqrt{K_\omega}} \left[ \sum_{i=0}^{N_1-1} \frac{J^i(c_0)}{\text{dist}(c_i, C) \text{dist}(c_i, S)} \right]^{-1}
\]
\[
\geq \frac{J^{N_1}(c_0)(K_\omega)^{5/6} - 1}{k_2
\]
\[
\geq \frac{J^{N_1}(c_0)(K_\omega)^{5/6}}{k_2}
\]
\[
= \frac{J^{N_1}(c_0)(K_\omega)^{1/3}}{k_2}
\]
\[
= k_3 (K_\omega)^{1/3} \quad \text{where } k_3 = \frac{J^{N_1}(c_0)}{k_2} > 0.
\]
\[ |h_a^{N_1+1}(I_{N_1}(c))| \geq J^{N_1}(h_a(c)) \cdot |h_a(I_{N_1}(c))| \]

Definition of \( I_p \)
\[ \geq \frac{1}{2} J^{N_1}(h_a(c)) \cdot |D_{N_1}(c_0) - D_{N_1+1}(h_a(c))| \]
\[ h_a(c) = c_0 \geq \frac{1}{4} J^{N_1}(c_0) |D_{N_1}(c_0)| \]
\[ (2) \geq k_4(K_\omega)^{1/3} \quad \text{where} \quad k_4 = k_3/4 > 0. \]

If \( K_\omega \) is large and \( a \in \Delta \), then \( |h_a^{N_1+1}(I_{N_1}(c))| > k_4(K_\omega)^{1/3} \gg 2\pi. \)

\[ \square \]

Remark 8.5. As \( K_\omega \) gets larger, the contracting regions get smaller and the dynamics is more and more expanding in most of the phase space. The recurrence to \( S \) is inevitable.

9. Proof of Theorem A: “large” strange attractors

The proof of Theorem A needs the results of Sections 6, 7 and 8. First of all, note that there is a correspondence between the set \( \Delta \) of Section 7 and the set \( \Delta_\lambda \) of statement of Theorem A:
\[ a = -K_\omega \ln \lambda \pmod{2\pi} \iff \lambda = \exp \left( \frac{a - 2k\pi}{K_\omega} \right), \quad \text{where} \quad k \in \mathbb{N}. \]

For \( \lambda \in \Delta_\lambda \), let \( B \subset \mathcal{U} \) a small ball centered at \( x_0 \in \mathcal{U} \) and radius \( \varepsilon > 0 \) and define
\[ B^* = B \setminus W^s(P_1). \]

It is clear that \( \text{Leb}_2(B) = \text{Leb}_2(B^*) > 0 \) since \( \text{Leb}_2(W^s(P_1)) = 0 \). The \( \omega \)-limit of \( B^* \) is the set \( W^u(P_2) \), parametrized by \( y = 0 \), whose dynamics is governed by the map \( h_a \) of Lemma 6.1. If \( K_\omega \) is large enough, then:

1. there exists a subset of \( B^* \) such that, after a finite number of iterations, its first component contains an interval with a critical point of \( h_a \) whose orbit has a positive Lyapunov exponent (combination of Lemma 8.2 and Item (2) of Lemma 7.2). Indeed,\n\[ \lambda(h_a, c) = \lim_{n \in \mathbb{N}} \frac{1}{n} |(h_a^n)'(h_a(c))| \geq \frac{1}{1000} \ln(K_\omega) > 0. \]

2. Lemma 8.4 says that there exists a subset of the projection of \( B^* \) whose \( \omega \)-limit covers the entire \( S^1 \). More precisely, by Remark 8.5
\[ |h_a^{N_1+1}(I_{N_1}(c))| \gg 2\pi. \]

This finishes the proof of Theorem A.

Let \( \Gamma_\lambda \) be the heteroclinic network defined in Section 3.4; \( \lambda \in \Delta_\lambda \) and \( K_\omega \) sufficiently large. Fix an infinite admissible path \( \sigma^\infty \) on \( \Gamma_\lambda \) and let \( V_1 \) be any small tubular neighbourhood of \( \Gamma_\lambda \). Any small ball (open set) \( B \) contained in \( V_1 \cap \text{Out}(P_2) \) shadows \( W^u(P_2) \cap \text{Out}(P_2) \), after a finite number of iterations, as a consequence of Theorem A. This means that there exists a subset of \( B \setminus W^s(P_1) \) that intersects \( V_1 \cap W^u(P_2) \) and spreads around all possible connections leaving \( P_2 \) and \( P_1 \). This proves infinite switching. The phenomenon is realized by all initial conditions lying in \( B^* \cap \mathbb{G}_\lambda^n(V_1 \cap \text{Out}(P_2)) \), where \( n \in \mathbb{N} \), which has positive Lebesgue measure.

11. An example

This research article has been motivated by the following example introduced in [27]. Some preliminaries about symmetries of a vector field may be found in [19, 27]. For \( \lambda \in [0, 1] \), our object of study is the one-parameter family of vector fields on \( \mathbb{R}^4 \)

\[
x = (x_1, x_2, x_3, x_4) \in \mathbb{R}^4 \quad \mapsto \quad g_\lambda(x)
\]

defined for each \( x = (x_1, x_2, x_3, x_4) \in \mathbb{R}^4 \) by

\[
\begin{align*}
\dot{x}_1 &= x_1(1 - r^2) - \omega x_2 - \alpha_1 x_1 x_4 + \alpha_2 x_1 x_3^2 \\
\dot{x}_2 &= x_2(1 - r^2) + \omega x_1 - \alpha_1 x_2 x_4 + \alpha_2 x_2 x_3^2 \\
\dot{x}_3 &= x_3(1 - r^2) + \alpha_1 x_3 x_4 + \alpha_2 x_3 x_2^2 + \lambda x_1 x_2 x_4 \\
\dot{x}_4 &= x_4(1 - r^2) - \alpha_1 x_4^2 - x_1^2 - x_2^2 - \alpha_2 x_4(x_1^2 + x_2^2 + x_3^2) - \lambda x_1 x_2 x_3
\end{align*}
\]

(11.1)

where \( \dot{x} = \frac{\partial x_i}{\partial t}, \quad r^2 = x_1^2 + x_2^2 + x_3^2 + x_4^2 \), and

\[
\omega > 0, \quad \beta < 0 < \alpha, \quad \beta^2 < 8\alpha^2 \quad \text{and} \quad |\beta| < |\alpha|.
\]

The unit sphere \( \mathbb{S}^3 \subset \mathbb{R}^4 \) is invariant under the corresponding flow and every trajectory with nonzero initial condition is forward asymptotic to it (cf. [27]). Indeed, if \( \langle \cdot, \cdot \rangle \) denotes the usual inner product in \( \mathbb{R}^4 \), then it is easy to check that:

**Lemma 11.1.** For every \( x \in \mathbb{S}^3 \) and \( \lambda \in [0, 1] \), we have \( \langle g_\lambda(x), x \rangle = 0 \).

The origin is repelling since all eigenvalues of \( Dg_\lambda(0, 0, 0, 0) \) have positive real part (where \( \lambda \in [0, 1] \)). The vector field \( g_0 \) is equivariant under the action of the compact Lie group \( \text{SO}(2)(\gamma_\psi) \oplus \mathbb{Z}_2(\gamma_2) \), where \( \text{SO}(2)(\gamma_\psi) \) and \( \mathbb{Z}_2(\gamma_2) \) act on \( \mathbb{R}^4 \) as

\[
\gamma_\psi(x_1, x_2, x_3, x_4) = (x_1 \cos \psi - x_3 \sin \psi, x_1 \sin \psi + x_2 \cos \psi, x_3, x_4), \quad \psi \in [0, 2\pi]
\]

given by a phase shift \( \theta \mapsto \theta + \psi \) in the first two coordinates, and

\[
\gamma_2(x_1, x_2, x_3, x_4) = (x_1, x_2, -x_3, x_4).
\]

By construction, \( \lambda \) is the controlling parameter of the \( \mathbb{Z}_2(\gamma_2) \)–symmetry breaking but keeping the \( \text{SO}(2)(\gamma_\psi) \)–symmetry, where

\[
\gamma_\tau(x_1, x_2, x_3, x_4) = (-x_1, -x_2, x_3, x_4).
\]

When restricted to the sphere \( \mathbb{S}^3 \), for every \( \tau_1, \tau_2 \in [0, 1] \), the flow of \( g_\lambda \) has two equilibria

\[
P_1 = (0, 0, 0, +1) \quad \text{and} \quad P_2 = (0, 0, 0, -1),
\]

which are hyperbolic saddle-foci. The linearization of \( g_\lambda \) at \( P_1 \) and \( P_2 \) has eigenvalues

\[
-(\alpha - \beta) \pm \omega i, \quad \alpha + \beta \quad \text{and} \quad (\alpha + \beta) \pm \omega i, \quad -(\alpha - \beta)
\]
respectively. Using the terminology of Section 3, we get:

\begin{equation}
C_1 = C_2 = \alpha - \beta > 0, \quad E_1 = E_2 = \alpha + \beta > 0, \quad \delta_1 = \delta_2 = \frac{\alpha - \beta}{\alpha + \beta} > 1 \quad (11.2)
\end{equation}

and

\begin{equation}
K_\omega = \frac{2\alpha\omega}{(\alpha + \beta)^2} > 0. \quad (11.3)
\end{equation}

The 1D-connections are contained in:

\begin{align*}
W^u(P_1) \cap S^3 & = \overline{W^s(P_2)} \cap S^3 = \text{Fix(SO}(2)(\gamma_\psi)) \cap S^3 \\
& = \{(x_1, x_2, x_3, x_4) : x_1 = x_2 = 0, x_3^2 + x_4^2 = 1\}
\end{align*}

and the 2D-connection is contained in

\begin{align*}
W^u(P_2) \cap S^3 & = \overline{W^s(P_1)} \cap S^3 = \text{Fix(Z}_2(\gamma_2)) \cap S^3 \\
& = \{(x_1, x_2, x_3, x_4) : x_1^2 + x_2^2 + x_4^2 = 1, x_3 = 0\}.
\end{align*}

Figure 5. Projection into three coordinates of the solution of \((11.1)\) with initial condition \((0.01; 0.01; 0.01; 1)\) near \(W^u(P_2)\), with \(\lambda = 0.1, \omega = 1, \alpha = 1, \beta = -0.1, \) and \(t \in [0, 10000]\). Red stars represent the equilibria \(P_1\) and \(P_2\). The greatest Lyapunov exponent is \(0.0004 \geq 0\).

The two-dimensional invariant manifolds of \(P_1\) and \(P_2\) are contained in the two-sphere \(\text{Fix(Z}_2(\gamma_2)) \cap S^3\). It is precisely the symmetry \(Z_2(\gamma_2)\) that forces the two-invariant manifolds \(W^u(P_2)\) and \(W^s(P_1)\) to coincide. We denote by \(\Gamma\) the heteroclinic network formed by the two equilibria, the two connections \([P_1 \rightarrow P_2]\) and the sphere \([P_2 \rightarrow P_1]\). By the way the vector field \(g_\lambda\) is constructed, the equilibria \(P_1\) and \(P_2\) have the same chirality. Therefore:

**Lemma 11.2.** If \(\lambda = 0\), the flow of \((11.1)\) satisfies \((H1)-(H5)\) described in Section 3.7.
Figure 6. Projection into three coordinates of the solution of (11.1) with initial condition $$(0.01; 0.01; 0.01; 1)$$ near $W^u(P_2)$, with $\lambda = 0.1$, $\omega = 10$, $\alpha = 1$, $\beta = -0.1$, and $t \in [0, 10000]$. The greatest Lyapunov exponent is $0.139 > 0$.

For $\lambda = 0$, the flow of (11.1) exhibits an asymptotically stable heteroclinic network $\Gamma$ associated to $P_1$ and $P_2$. Since all the heteroclinic connections are contained in fixed point subspaces, there is no switching near $\Gamma$. The parameter $\lambda$ plays the role of $\text{(H6)}$–$\text{(H7)}$, after possible rescaling.

Lemma 11.3. [27, Appendix A] For $\lambda > 0$ small, the following conditions hold:

1. $W^u(P_2)$ and $W^s(P_1)$ intersect transversely.
2. There are two one-dimensional connections from $P_1$ to $P_2$.

When $\lambda > 0$, although we break the $\mathbb{SO}(2)(\gamma_\psi)$-equivariance, the $\mathbb{Z}_2(\gamma_\pi)$-symmetry is preserved. This is why the connections lying in $x_1 = x_2 = 0$ persist. For $\lambda > 0$, let us denote by $\Gamma_\lambda$ the emerging heteroclinic network and $\mathcal{U}$ a small absorbing domain of $\Gamma$. As a consequence of Theorems [A] and [B] we may easily conclude that:

Corollary 11.4. With respect to the dynamics of (11.1), there exists $\omega^0 \gg 1$ such that if $\omega > \omega^0$, then:

1. There exists a set $\Delta_\lambda \subset [0, \lambda_0]$ ($\lambda_0$ small) with positive Lebesgue measure such that if $\lambda \in \Delta_\lambda$, then the flow of $g_\lambda$ contains a “large” strange attractor;
(2) there exists a set $\Delta_\lambda \subset [0, \lambda_0]$ ($\lambda_0$ small) with positive Lebesgue measure such that if $\lambda \in \Delta_\lambda$, then the network $\Gamma_\lambda$ exhibits abundant infinite switching.

Abundant switching is realized by any non-empty ball of initial conditions lying in $\mathcal{U}$.

Remark 11.5. The generic Hypothesis (H8) for model (11.1) is a technical point that is impossible to be rigorously checked.

Numerical simulations of (11.1) in Figures 5 and 6 for $\lambda > 0$ suggest the existence of strange attractors and the effect of the parameter $\omega$. We can observe that when $\omega = 10$ (large), then the non-wandering set associated to the initial condition $(0.01; 0.01; 0.01; 1)$ covers the sphere $W^u(P_2)$. This set cannot attract open sets of initial conditions (because $W^s(P_1)$ is ubiquitous in the absorbing domain), although it attracts sets with positive Lebesgue measure. Solutions seem to visit the connections leaving $P_2$ in a uniformly distributed manner.

Since $W^u(P_2)$ plays an essential role in the construction of the strange attractor, we chose the initial condition $(0.01; 0.01; 0.01; 1)$ close to $W^u(P_2)$ to collect the main dynamical properties of the maximal attracting set of (11.1). The computer experiments have been performed using Matlab (R2021b, Mathworks, Natick, MA, USA) and the Lyapunov exponents have been computed using the method described in Section 5.3 of [12].

12. Discussion and concluding remarks

This paper finishes the discussion about the dynamics of the class of examples presented in [21, 23] and numerically explored in [27]. Our starting point is a one-parameter family of ordinary differential equations (3.1) defined in the unit sphere $S^3$ with two saddle-foci whose organising center ($\lambda = 0$) shares all the invariant manifolds, forming an attracting heteroclinic network $\Gamma$. When $\lambda \neq 0$, we assume that the one-dimensional connections persist, and the two dimensional invariant manifolds intersect transversely, forming a heteroclinic tangle $\Gamma_\lambda$. The existence of infinite switching near $\Gamma_\lambda$ follows the reasoning of [5] but the Lebesgue measure of the set of initial conditions realising switching was unknown. The main contribution of this paper is twofold:

(1) First, in Theorem A, we prove that, if the twisting number $K_\omega$ is large enough, then for a subset of $[0, \lambda_0]$ ($\lambda_0 > 0$ is small) with positive Lebesgue measure, the dynamics of the first return map $G_\lambda$ exhibits non-uniformly hyperbolic strange attractors winding around the annulus $\text{Out}(P_2)$ (after a given transient) – i.e. they have “large” strange attractors. The $\omega$-limit of almost all points in $\mathcal{U}$ contains the set $W^u(P_2)$. These strange attractors have one positive Lyapunov exponent, are non-uniformly expanding and are not robustly transitive.

(2) Secondly, the proof of “large” strange attractors allows us to prove Theorem B: the $\omega$-limit of points lying in any small ball in $\mathcal{U}$ (absorbing domain of $\Gamma$) contains the whole set $W^u(P_2) \cap \text{Out}(P_2)$, allowing the visit of any admissible sequence of heteroclinic connections. The original network structure will be observed in the long term dynamics even though $\Gamma_\lambda$ is not attracting, an idea already pointed out by the authors.
of [19] in other setting.

These dynamical phenomena are caused essentially by three main ingredients: the existence of saddle-foci in the network, the transverse intersection of $W^u(P_2)$ and $W^s(P_1)$ and the fact that they unfold a coincidence at $\lambda = 0$. In the example discussed in Section 11, this coincidence is caused by the $\mathbb{SO}(2)$-equivariance, where $\omega > 0$ is the unique parameter that matter to prompt “large” strange attractors.

Our findings have the same flavour to those of [30], even though Hypothesis (H7) is different and the classical theory of [32] does not hold in the case under consideration. As far as we know, there is no analogue of the effect of singularities of the singular limit in previous studies about infinite switching.

We have made use of the critical interval constructed by [31] to realize that, after a finite number of iterations of the singular limit $h_a$, any small ball of initial conditions in $\mathrm{Out}(P_2)$ will cover the whole $S^1$ infinitely many times. The idea of abundant infinite switching is also implicit in Section 3.2 of [19]; if $\omega > 0$ is sufficiently large, then the range of the angular coordinate covers at least $[0, 2\pi]$. See also Figure 5 of [19] where the length of the line segment is chosen such that its image covers the full range of values of the angular component.

This article makes part of a systematic study of Bykov cycles bifurcations and finishes the generic study of their dynamical properties. The next natural problem is the study of statistical and ergodic properties of this class of examples, whose singular cycle has an attracting component and another with an unbounded derivative. Since the classical work by [32] does not hold in this class of examples, its adaptation is a big challenge.

For $\lambda \in [0, \lambda_0] \setminus \Delta_\lambda$ ($\lambda_0$ small), we guess that the non-wandering set of Lebesgue almost all solutions of (3.1) has zero topological entropy. We defer the formal proof of this conjecture for a future work.
