LANGEVIN DYNAMICS BASED ALGORITHM E-TH:=O POULA FOR STOCHASTIC OPTIMIZATION PROBLEMS WITH DISCONTINUOUS STOCHASTIC GRADIENT

DONG-YOUNG LIM, ARIEL NEUFELD, SOTIRIOS SABANIS, AND YING ZHANG

ABSTRACT. We introduce a new Langevin dynamics based algorithm, called e-TH:=O POULA, to solve optimization problems with discontinuous stochastic gradients which naturally appear in real-world applications such as quantile estimation, vector quantization, CVaR minimization, and regularized optimization problems involving ReLU neural networks. We demonstrate both theoretically and numerically the applicability of the e-TH:=O POULA algorithm. More precisely, under the conditions that the stochastic gradient is locally Lipschitz in average and satisfies a certain convexity at infinity condition, we establish non-asymptotic error bounds for e-TH:=O POULA in Wasserstein distances and provide a non-asymptotic estimate for the expected excess risk, which can be controlled to be arbitrarily small. Three key applications in finance and insurance are provided, namely, multi-period portfolio optimization, transfer learning in multi-period portfolio optimization, and insurance claim prediction, which involve neural networks with (Leaky)-ReLU activation functions. Numerical experiments conducted using real-world datasets illustrate the superior empirical performance of e-TH:=O POULA compared to SGLD, ADAM, and AMSGrad in terms of model accuracy.

1. INTRODUCTION

A wide range of problems in economics, finance, and quantitative risk management can be represented as stochastic optimization problems. Traditional approaches to solve such problems typically face the curse of dimensionality in practical settings, which motivates researchers and practitioners to apply machine learning approaches to obtain approximated solutions. Consequently, deep learning have been widely adopted to almost all aspects in, e.g., financial applications including option pricing, implied volatility, prediction, hedging, and portfolio optimization [2, 4, 6, 9, 18, 26, 30, 41, 47, 48, 58, 59], and applications in insurance [10, 21, 24, 25, 33, 34, 38, 45, 49, 60, 62, 64]. While the aforementioned results justify the use of deep neural networks through the universal approximation theorem, it is not a trivial problem to train a deep neural network, which is equivalent to minimizing an associated loss function, using efficient optimization algorithms. Stochastic gradient descent (SGD) and its variants are popular methods to solve such non-convex and large scale optimization problems. However, it is well known that SGD methods are only proven to converge to a stationary point in non-convex settings. Despite the lack of theoretical guarantees for the SGD methods, the literature on deep learning in finance, insurance, and their related fields heavily rely on popular optimization methods such as SGD and its variants including, e.g., ADAM [35] and AMSGrad [51]. In [31], the author explicitly highlights the importance of research on stochastic optimization methods for problems in finance: ‘The choice of optimisation engine in deep learning is vitally important in obtaining sensible results, but a topic rarely discussed (at least within the financial mathematics community)’. The aim of this paper is thus to bridge the theoretical gap and to extend the empirical understanding of training deep learning models in applications in finance and insurance. We achieve these by investigating the properties of a newly proposed algorithm, i.e., the extended Tamed Hybrid ε-Order POLygonal Unadjusted Langevin Algorithm (e-TH:=O POULA), developed based on TH:=O POULA proposed in [39], which can be applied to optimization problems with discontinuous stochastic gradients including quantile estimation, vector quantization, CVaR minimization, and regularized optimization problems involving ReLU neural networks, see, e.g., [7, 19, 40, 53].

Key words and phrases. Langevin dynamics based algorithm, discontinuous stochastic gradient, non-convex stochastic optimization, non-asymptotic convergence bound, artificial neural networks, ReLU activation function, taming technique, super-linearly growing coefficients.

We consider the following optimization problem:

\[
\text{minimize } \mathbb{R}^d \ni \theta \mapsto u(\theta) := \mathbb{E}[U(\theta, X)],
\]

where \( U : \mathbb{R}^d \times \mathbb{R}^m \to \mathbb{R} \) is a measurable function, and \( X \) is a given \( \mathbb{R}^m \)-valued random variable with probability law \( \mathcal{L}(X) \). To obtain approximate minimizers of (1), one of the approaches is to apply the stochastic gradient Langevin dynamics (SGLD) algorithm introduced in [61], which can be viewed as a variant of the Euler discretization of the Langevin SDE defined on \( t \in [0, \infty) \) given by

\[
dZ_t = -\nabla u(\theta) dt + \sqrt{2\beta^{-1}} dB_t, \quad Z_0 = \theta_0,
\]

where \( \theta_0 \) is an \( \mathbb{R}^d \)-valued random variable, \( h := \nabla u, \beta > 0 \) is the inverse temperature parameter, and \((B_t)_{t \geq 0}\) is a \( d\)-dimensional Brownian motion. The associated stochastic gradient of the SGLD algorithm is defined as a measurable function \( H : \mathbb{R}^d \times \mathbb{R}^m \to \mathbb{R}^d \) which satisfies \( h(\theta) = \mathbb{E}[H(\theta, X)] \) for all \( \theta \in \mathbb{R}^d \). One notes that, under mild conditions, the Langevin SDE (2) admits a unique invariant measure \( \pi_\beta \) concentrated around \( \min_{\beta} \pi_\beta \) with large \( \beta \). The convergence properties of the SGLD algorithm to \( \pi_\beta \) in suitable distances have been well studied in the literature, under the conditions that the (stochastic) gradient of \( u \) is globally Lipschitz continuous and satisfies a (local) dissipativity or convexity at infinity condition, see, e.g., [8, 11, 50, 63, 65] and references therein. Recent research focuses on the relaxation of the global Lipschitz condition imposed on the (stochastic) gradient of \( u \) so as to accommodate optimization problems involving neural networks. However, the SGLD algorithm is unstable when applying to objective functions with highly non-linear (stochastic) gradients, and the absolute moments of the approximations generated by the SGLD algorithm could diverge to infinity at a finite time point, see [27].

To address this issue, [42] proposed a tamed unadjusted stochastic Langevin algorithm (TUSLA), which is obtained by applying the taming technique, developed in, e.g., [5, 28, 54, 55], to the SGLD algorithm. Convergence results of TUSLA are provided in [42] under the condition that the (stochastic) gradient of \( u \) is polynomially Lipschitz growing. In [40], the applicability of TUSLA is further extended to the case where the (stochastic) gradient of \( u \) is discontinuous, and the polynomial Lipschitz condition is replaced by a more relaxed locally Lipschitz in average condition. The latter condition is similar to [7, Eqn. (6)] and [19, H4], which well accommodates the optimization problems with ReLU neural networks. One may also refer to [7, 14, 15, 19, 43] for the convergence results of the Langevin dynamics based algorithms with discontinuous (stochastic) gradients.

Despite their established theoretical guarantees, TUSLA and other Langevin dynamics based algorithms are less popular in practice, especially when training deep learning models, compared to adaptive learning rate methods including ADAM and AMSGrad. This is due to the superior performance of the latter group of algorithms in terms of the training speed. In [39], a new class of Langevin dynamics based algorithms, namely TH\( \epsilon \) POULA, is proposed based on the advances of polygonal Euler approximations, see [36, 37]. More precisely, the design of TH\( \epsilon \) POULA relies on a combination of a componentwise taming function and a componentwise boosting function, which simultaneously address the exploding and vanishing gradient problems. Furthermore, such a design allows TH\( \epsilon \) POULA to convert from an adaptive learning rate method to a Langevin dynamics based algorithm when approaching an optimal point, preserving the feature of a fast training speed of the former and the feature of a good generalization of the latter. In addition, [39] provides a convergence analysis of TH\( \epsilon \) POULA for non-convex regularized optimization problems. Under the condition that the (stochastic) gradient is locally Lipschitz continuous, non-asymptotic error bounds for TH\( \epsilon \) POULA in Wasserstein distances are established, and a non-asymptotic estimate for the expected excess risk is provided. However, the local Lipschitz condition fails to accommodate optimization problems with discontinuous stochastic gradients.

In this paper, we propose the algorithm e-TH\( \epsilon \) POULA, which is an extension of TH\( \epsilon \) POULA (developed in [39]) as explained below. We aim to demonstrate both theoretically and numerically the applicability of e-TH\( \epsilon \) POULA for optimization problems with discontinuous stochastic gradients. From a theoretical point of view, our goal is to provide theoretical guarantees for e-TH\( \epsilon \) POULA to find approximate minimizers of \( u \) with discontinuous stochastic gradient. More concretely, we aim to relax the local Lipschitz condition, and replace it with a local Lipschitz in average condition, see Assumption 2. In addition, [39] considers regularized optimization problems which assume a certain structure of the stochastic gradients of the corresponding objective functions. More precisely, [39] assumes that \( u(\theta) := g(\theta) + \eta|\theta|^{2r+1}/(2r+1), \theta \in \mathbb{R}^d \), where \( g : \mathbb{R}^d \to \mathbb{R}, \eta > 0, \) and \( r > 0 \). The
second term on the RHS of \( u \) is the regularization term, and the stochastic gradient of \( u \), denoted by \( H : \mathbb{R}^d \times \mathbb{R}^m \to \mathbb{R}^d \), is given by \( H(\theta, x) = G(\theta, x) + \eta \theta |\theta|^{2r} \) where \( \nabla G(\theta) = \mathbb{E}[G(\theta, X)] \). We aim to generalize the structure of \( H \) by replacing \( \eta \theta |\theta|^{2r} \) with a measurable function \( F : \mathbb{R}^d \times \mathbb{R}^m \to \mathbb{R}^d \) which satisfies a local Lipschitz condition and a convexity at infinity condition, see (7) and Assumptions 3 and 4. In our setting, the gradient of the regularization term is a particular feasible example for the choice of \( F \). In addition to the aforementioned assumptions, by further imposing conditions on the initial value of e-TH\( : \) POULA and on the second argument of \( H \), see Assumption 1, we establish non-asymptotic error bounds of e-TH\( : \) POULA in Wasserstein distances and a non-asymptotic upper estimate of the expected excess risk given by \( \mathbb{E}[u(\theta)] = \inf_{\theta \in \mathbb{R}^d} u(\theta) \) with \( \theta \) denoting an estimator generated by e-TH\( : \) POULA, which can be controlled to be arbitrarily small. From a numerical point of view, we illustrate the powerful empirical performance of e-TH\( : \) POULA by providing key examples in finance and insurance using real-world datasets, i.e., the multi-period portfolio optimization, transfer learning in the multi-period portfolio optimization, and the insurance claim prediction via neural network-based non-linear regression. Numerical experiments show that e-TH\( : \) POULA outperforms SGLD, ADAM, and AMSGrad in terms of training accuracy.

We conclude this section by introducing some notation. For \( a, b \in \mathbb{R} \), denote by \( a \wedge b = \min\{a, b\} \) and \( a \vee b = \max\{a, b\} \). Let \( (\Omega, \mathcal{F}, P) \) be a probability space. We denote by \( \mathbb{E}[Z] \) the expectation of a random variable \( Z \). For \( 1 \leq p < \infty \), \( L^p \) is used to denote the usual space of \( p \)-integrable real-valued random variables. Fix integers \( d, m \geq 1 \). For an \( \mathbb{R}^d \)-valued random variable \( Z \), its law on \( \mathcal{B}(\mathbb{R}^d) \), i.e., the Borel sigma-algebra of \( \mathbb{R}^d \), is denoted by \( \mathcal{L}(Z) \). For a positive real number \( a \), we denote by \( \lfloor a \rfloor \) its integer part, and \( \lceil a \rceil := \lfloor a \rfloor + 1 \). The Euclidean scalar product is denoted by \( \langle \cdot, \cdot \rangle \), with \( | \cdot | \) standing for the corresponding norm (where the dimension of the space may vary depending on the context). For any integer \( q \geq 1 \), let \( \mathcal{P}(\mathbb{R}^q) \) denote the set of probability measures on \( \mathcal{B}(\mathbb{R}^q) \). For \( \mu \in \mathcal{P}(\mathbb{R}^d) \) and for a \( \mu \)-integrable function \( f : \mathbb{R}^d \to \mathbb{R} \), the notation \( \mu(f) := \int_{\mathbb{R}^d} f(\theta) d\mu(\theta) \) is used. For \( \mu, \nu \in \mathcal{P}(\mathbb{R}^d) \), let \( \mathcal{C}(\mu, \nu) \) denote the set of probability measures \( \zeta \in \mathcal{B}(\mathbb{R}^{2d}) \) such that its respective marginals are \( \mu, \nu. \) For two Borel probability measures \( \mu \) and \( \nu \) defined on \( \mathbb{R}^d \) with finite \( p \)-th moments, the Wasserstein distance of order \( p \geq 1 \) is defined as

\[
W_p(\mu, \nu) := \left( \inf_{\zeta \in \mathcal{C}(\mu, \nu)} \int_{\mathbb{R}^d} \int_{\mathbb{R}^d} |\theta - \tilde{\theta}|^p \zeta(d\theta, d\tilde{\theta}) \right)^{1/p}.
\]

2. e-TH\( : \) POULA: SETTING AND DEFINITION

2.1. Setting. Let \( U : \mathbb{R}^d \times \mathbb{R}^m \to \mathbb{R} \) be a Borel measurable function, and let \( X \) be an \( \mathbb{R}^m \)-valued random variable defined on the probability space \( (\Omega, \mathcal{F}, P) \) with probability law \( \mathcal{L}(X) \) satisfying \( \mathbb{E}[|U(\theta, X)|] < \infty \) for all \( \theta \in \mathbb{R}^d \). We assume that \( u : \mathbb{R}^d \to \mathbb{R} \) defined by \( u(\theta) := \mathbb{E}[U(\theta, X)] \), \( \theta \in \mathbb{R}^d \), is a continuously differentiable function, and denote by \( h := \nabla u \) its gradient. In addition, for any \( \beta > 0 \), we define

\[
\pi_\beta(A) := \frac{\int_{\mathbb{R}^d} e^{-\beta u(\theta)} d\theta}{\int_{\mathbb{R}^d} e^{-\beta u(\theta)} d\theta}, \quad A \in \mathcal{B}(\mathbb{R}^d),
\]

where we assume \( \int_{\mathbb{R}^d} e^{-\beta u(\theta)} d\theta < \infty \).

Denote by \( (\mathcal{G}_n)_{n \in \mathbb{N}_0} \) a given filtration representing the flow of past information, and denote by \( \mathcal{G}_\infty := \sigma(\bigcup_{n \in \mathbb{N}_0} \mathcal{G}_n) \). Moreover, let \( (X_n)_{n \in \mathbb{N}_0} \) be a \( (\mathcal{G}_n) \)-adapted process such that \( (X_n)_{n \in \mathbb{N}_0} \) is a sequence of i.i.d. \( \mathbb{R}^m \)-valued random variables with probability law \( \mathcal{L}(X) \). In addition, let \( (\xi_n)_{n \in \mathbb{N}_0} \) be a sequence of independent standard \( d \)-dimensional Gaussian random variables. We assume throughout the paper that the \( \mathbb{R}^d \)-valued random variable \( \theta_0 \) (initial condition), \( \mathcal{G}_\infty \), and \( (\xi_n)_{n \in \mathbb{N}_0} \) are independent.

Let \( H : \mathbb{R}^d \times \mathbb{R}^m \to \mathbb{R}^d \) be an unbiased estimator of \( h \), i.e., \( h(\theta) = \mathbb{E}[H(\theta, X_0)] \), for all \( \theta \in \mathbb{R}^d \), which takes the following form: for all \( \theta \in \mathbb{R}^d \), \( x \in \mathbb{R}^m \),

\[
H(\theta, x) := G(\theta, x) + F(\theta, x),
\]

where \( G = (G^{(1)}, \ldots, G^{(d)}) : \mathbb{R}^d \times \mathbb{R}^m \to \mathbb{R}^d \) and \( F = (F^{(1)}, \ldots, F^{(d)}) : \mathbb{R}^d \times \mathbb{R}^m \to \mathbb{R}^d \) are Borel measurable functions.

2.2. Algorithm. We define the extended Tamed Hybrid \( \varepsilon \)-Order POlygonal Unadjusted Langevin Algorithm (e-TH\( : \) POULA) by

\[
\theta_0^\lambda := \theta_0, \quad \theta_{n+1}^\lambda := \theta_n^\lambda - \lambda H_A(\theta_n^\lambda, X_{n+1}) + \sqrt{2\lambda h^{-1}} \xi_{n+1}, \quad n \in \mathbb{N}_0,
\]
where $\lambda > 0$ is the stepsize, $\beta > 0$ is the inverse temperature parameter, and where $H_\lambda(\theta, x)$ is defined, for all $\theta \in \mathbb{R}^d, x \in \mathbb{R}^m$, by

$$H_\lambda(\theta, x) := G_\lambda(\theta, x) + F_\lambda(\theta, x),$$

with $G_\lambda(\theta, x) = (G_\lambda^{(1)}(\theta, x), \ldots, G_\lambda^{(d)}(\theta, x))$ and $F_\lambda(\theta, x) = (F_\lambda^{(1)}(\theta, x), \ldots, F_\lambda^{(d)}(\theta, x))$ given by

$$G_\lambda^{(i)}(\theta, x) := \frac{G^{(i)}(\theta, x)}{1 + \sqrt{\lambda |G^{(i)}(\theta, x)|}} \left(1 + \frac{\sqrt{\lambda}}{\varepsilon + |G^{(i)}(\theta, x)|}\right), \quad F_\lambda^{(i)}(\theta, x) := \frac{F^{(i)}(\theta, x)}{1 + \sqrt{\lambda |\theta|^2 r}},$$

for any $i = 1, \ldots, d$ with fixed $0 < \varepsilon < 1, r > 0$.

**Remark 2.1.** Recall that the general form of the stochastic gradient Langevin dynamics (SGLD) algorithm is given by

$$\theta_n^{\text{SGLD}} := \theta_0, \quad \theta_{n+1}^{\text{SGLD}} := \theta_n^{\text{SGLD}} - \lambda H(\theta_n^{\text{SGLD}}, X_{n+1}) + \sqrt{2\lambda|\theta|^2} \xi_{n+1}, \quad n \in \mathbb{N}_0.$$

Therefore, e-TH\(\text{POULA}) is obtained by replacing $H$ in the SGLD algorithm with $H_\lambda$ given in (6)-(7). More precisely, one part of $H_\lambda$, i.e., $F_\lambda$, is obtained by multiplying $F$ with the taming factor $1 + \sqrt{\lambda |\theta|^2 r}$, while the other part of $H_\lambda$, i.e., $G_\lambda$, is defined by dividing $G$ componentwise with the taming factor $1 + \sqrt{\lambda |G^{(i)}(\theta, x)|}$ and, importantly, with the boosting function $1 + \frac{\sqrt{\lambda}}{\varepsilon + |G^{(i)}(\theta, x)|}$. One observes that, when $|G^{(i)}(\theta, x)|$ is small, the boosting function takes a large value, which, in turn, contributes to the step-size and helps prevent the vanishing gradient problem which occurs when the stochastic gradient is extremely small resulting in insignificant updates of the algorithm before reaching an optimal point, while the boosting function is close to one when $|G^{(i)}(\theta, x)|$ is large. Moreover, the design of $H_\lambda$ is motivated by the regularized optimization problems. In such a setting, $F$ corresponds to the gradient of the regularized term, and $G$ corresponds to the gradient of the original (non-regularized) objective function of a given optimization problem. The boosting function, together with the componentwise design of $G_\lambda$, thus significantly improve the training efficiency of e-TH\(\text{POULA}) as demonstrated numerically in Section 3.

**Remark 2.2.** We consider $H$ taking the form of (4) with $G$ containing discontinuities and $F$ being locally Lipschitz continuous (see also Assumptions 2 and 3 in Section 4) as it is satisfied by a wide range of real-world applications including quantile estimation, vector quantization, CVaR minimization, and regularized optimization problems involving ReLU neural networks, see, e.g., [7, 19, 40, 53].

### 3. Numerical Experiments

This section demonstrates the performance of e-TH\(\text{POULA}) by applying it to real-world applications arising in finance and insurance. In Section 3.1, we apply e-TH\(\text{POULA}) to approximately solve the problem of portfolio selection studied in [59] using neural networks, where e-TH\(\text{POULA}) is used for the training of the neural networks. Data sets are generated from popular models in finance such as Black-Scholes and Autoregressive models. Then, Section 3.2 discusses a transfer learning setting, based on the dynamic programming principle, in the context of portfolio selection with theoretical guarantees for the convergence of our proposed algorithm. Lastly, in Section 3.3, we consider a neural network-based nonlinear regression to predict insurance claims where French auto insurance claim data is used. Source code for all the experiments can be found at [https://github.com/DongyoungLim/eTHEOPOULA](https://github.com/DongyoungLim/eTHEOPOULA).

#### 3.1. Multi-period portfolio optimization.

This subsection discusses a deep learning approach proposed in [59] to solve multi-period portfolio optimization problems. The idea of the approach is to view a given portfolio optimization problem as a Markov Decision Process (MDP), and then approximate the optimal policy function of the MDP by means of neural networks. We train the corresponding neural networks using e-TH\(\text{POULA}) and showcase its performance also in comparison with other popular optimization algorithms for the training of neural networks.

Fix $K > 0$. Assume that the financial market is defined on a filtered probability space $(\Omega, \{\mathcal{F}_k\}_{k=0}^K, P)$, where $\mathcal{F}_0 = \{\emptyset, \Omega\}$, with finite time horizon $[0, K]$ where assets can be traded at discrete time points, $k = 0, 1, 2, \ldots, K - 1$. For each time point $k$, denote by $R_k \in \mathbb{R}^p$ the excess return vector of $p$ risky assets between the period $[k, k + 1)$, whereas the risk free return is denoted by $R_f$. Moreover, denote by $W_k \in \mathbb{R}$ the wealth of the portfolio at time point $k$. For positive integers $d$ and $p$, denote by $\mathcal{S} \subseteq \mathbb{R}^{d*}$ the set of possible states and $\mathcal{D} \subseteq \mathbb{R}^p$ the set of possible actions representing the proportion of current wealth
invested in each risky asset. Then, for any $k = 0, 1, \ldots, K - 1$, the evolution of the wealth between the time points $k$ and $k + 1$ is given by

$$W_{k+1} = W_k((g_k(s_k), R_k) + R_f),$$

where $g_k(\cdot) : S \rightarrow D$ is the investment control policy function on $p$ risky assets at time point $k$ and $s_k \in S$ is the state at time point $k$ which is $\mathcal{F}_k$-measurable. Moreover, we denote by $\mathcal{U}$ the set of admissible\footnote{The functions in $\mathcal{U}$ may satisfy certain bounding constraints, e.g., $D = \Pi_{i=1}^{p} [l_i, u_i]$ for some lower bounds $l = (l_1, \ldots, l_p)$ and upper bounds $u = (u_1, \ldots, u_p)$.} control functions.

In this setting, we are interested in finding the optimal portfolio selection of $p$ risky assets which maximizes the expected utility function of the terminal wealth $W_K$. The expected utility maximization problem can be written as a MDP problem as follows:

$$V_K(s_0) = \max_{g_0, \ldots, g_{K-1} \in \mathcal{U}} \mathbb{E} [\Psi(s_K)]$$

subject to:

$$s_{k+1} = \tilde{h}(s_k, g_k(s_k), \eta_k), \quad k = 0, 1, \ldots, K - 1,$$

where $\Psi(\cdot) : S \rightarrow \mathbb{R}$ is the objective function, $\tilde{h} : S \times D \times \mathbb{R}^m \rightarrow S$ with $m > 0$ is the transition function, and $\eta_k$ is an $\mathbb{R}^m$-valued $\mathcal{F}_{k+1}$-measurable random variable. We assume that each of the $\mathbb{R}^{d_t}$-valued state variable $s_k$ contains (in one component) the wealth $W_k$, see, e.g., the autoregressive (AR) (1) model below. Furthermore, we set the quadratic utility function as the objective function, which is given by $\Psi(s_k) := U(W_k) = -(W_k - \gamma)^2$ for some fixed $\gamma > 0$.

We solve the MDP problem (9) via the deep learning approach proposed in [59]. We briefly introduce the approach to make our paper self-contained. Denote by $\mathcal{G}_\nu$ the set of standard feedforward neural networks with two hidden layers, which is given explicitly by

$$\mathcal{G}_\nu = \{ f : \mathbb{R}^{d_s} \rightarrow \mathbb{R}^p | f(x) = \tanh(K_3 z + b_3), z = \sigma(K_2 y + b_2), \}
= \sigma(K_1 x + b_1), K_1 \in \mathbb{R}^{p \times d_s}, K_2 \in \mathbb{R}^{p \times \nu}, K_3 \in \mathbb{R}^{\nu \times p}, b_1, b_2, b_3 \in \mathbb{R},$$

where $\nu$ denotes the number of neurons on each layer of the neural network, $\tanh(x)$, for any $x \in \mathbb{R}^p$, is the hyperbolic tangent function at $x$ applied componentwise, and $\sigma(y) = \max\{0, y\}$, $y \in \mathbb{R}^p$, is the ReLU activation function at $y$ applied componentwise.

For any matrix $M \in \mathbb{R}^{aM \times bM}$ with $aM, bM > 0$, denote by $[M]$ the vector of all elements in $M$. Moreover, for any $k = 0, 1, \ldots, K - 1$, denote by $g_k(\cdot; \theta_k) : \mathbb{R}^{d_t} \rightarrow \mathbb{R}^p$ the approximated policy function at time $k$ using a neural network with its structure defined in with (10), where $\theta_k = (b_1, b_2, b_3, [K_1], [K_2], [K_3]) \in \nu (d_s + \nu + p + 2) + p$ denotes the parameter of the neural network. Then\footnote{We refer to [59] for the verification of the approximation.}, the MDP problem (9) can be approximated by restricting $g_k(\cdot; \theta_k) \in \mathcal{G}_\nu$:

$$-V_K(s_0) := V_K(s_0) \approx V_K^\nu(s_0) = \min_\theta \mathbb{E} [-\Psi(s_K^\nu(\zeta; \theta))],$$

where $\zeta := (s_0, \eta_0, \ldots, \eta_{K-1})$ denotes the vector of the initial state variable and all the random variables throughout the trading time horizon $[0, K]$, and where $s_K^\nu(\zeta; \theta)$ is recursively defined, for $k = 0, 1, \ldots, K - 1$, by

$$s_{k+1} = \tilde{h}(s_k, g_k(s_k; \theta_k), \eta_k), \quad g_k(\cdot; \theta_k) \in \mathcal{G}_\nu$$

with $s_K^\nu(\zeta; \theta) := s_K, \theta = (\theta_0, \ldots, \theta_{K-1}) \in \mathbb{R}^{d}$ being the parameter for the neural networks, $d := K(\nu(d_s + \nu + p + 2) + p)$, and $\mathcal{G}_\nu$ given\footnote{In the implementation stage, one might need to perform suitable scalar addition and multiplication for the neural networks in $\mathcal{G}_\nu$ so that they also satisfy the bounding constraints specified for functions in $\mathcal{U}$.} in (10).

We test the performance of e-TH\footnote{The functions in $\mathcal{U}$ may satisfy certain bounding constraints, e.g., $D = \Pi_{i=1}^{p} [l_i, u_i]$ for some lower bounds $l = (l_1, \ldots, l_p)$ and upper bounds $u = (u_1, \ldots, u_p)$.} POULA in comparison with other popular stochastic optimization algorithms such as SGLD defined in (8), ADAM, and AMSGrad by solving the optimization problem (11) under two different asset return models: the (discrete-time version of) Black-Scholes model and the AR(1) model. Moreover, we provide extensive numerical experiments with different market parameters and different sizes of neurons to demonstrate the efficiency of our algorithm.

Black-Scholes model. For any matrix $M \in \mathbb{R}^{p \times p}$, denote by $\text{diag}(M) := (M_{11}, \ldots, M_{pp})$ the vector of the diagonal elements of $M$, and denote by $M^\top$ its transpose. Denote by $I_p$ the $p \times p$ identity matrix. For any $k = 0, \ldots, K - 1$, we consider the following (discrete-time) Black-Scholes model analyzed in [59] for the excess return $R_k$:

$$R_k = \exp \left( \left( \tilde{r} \mathbb{1} + \tilde{\lambda} \lambda - \frac{1}{2} \text{diag}(\Sigma \Sigma^\top) \right) \Delta + \sqrt{\Delta} \Sigma \epsilon_k \right) - R_f \mathbb{1},$$

where $\tilde{r} \in \mathbb{R}$, $\mathbb{1} = (1, \ldots, 1) \in \mathbb{R}^p$, $\Sigma \in \mathbb{R}^{p \times p}$, $\tilde{\lambda} \in \mathbb{R}^p$, $\Delta > 0$ is a constant rebalancing time period, $\epsilon_k, k = 0, \ldots, K - 1$, are i.i.d. $p$-dimensional Gaussian vectors with mean 0 and covariance $I_p$, i.e., $\epsilon_k \sim N_p(0, I_p)$, and $R_f := \exp(\tilde{r} \Delta)$ denotes the risk free return. In this setting, the excess returns $\{R_k\}_{k=0}^{K-1}$ are i.i.d.. Then, the equivalent optimization problem to the MDP problem (9) in the Black-Scholes model can be written as follows:

$$V_K(s_0) = \min_{g_0, \ldots, g_{K-1} \in \mathcal{U}} \mathbb{E}[-U(W_K)]$$

s.t. $W_{k+1} = W_k(g_k(s_k), R_k) + R_f$, $k = 0, 1, \ldots, K - 1$.

where $s_k := W_k$, $d_k := 1$, $\eta_k := R_k$, $\mathcal{U} := p$, and $\tilde{h}(s_k, g_k(s_k), \eta_k) := W_k(g_k(s_k), R_k) + R_f$.

We approximate the optimization problem (14) using the deep learning approach (11). More precisely, we train $K$ neural networks defined in (12). Each neural network is a standard feedforward neural network with two hidden layers and $\nu$ neurons on each layer as defined in (10). Three different simulation settings of the Black-Scholes model are summarized in Table 1. The benchmark solutions are computed using the continuous Hamilton-Jacobi-Bellman (HJB) equation as adopted in [59]. Moreover, similar to [59], the models are run for 100 steps with batch size of 128. For each step, 20,000 training samples are generated and 157 iterations ($= \lceil 20,000/128 \rceil$) are performed to train the models. Then, the test score is computed using 20,000 test samples. In addition, three different numbers of $\nu$ are tested for each experimental setting: for $p = 5$: $\nu = \{1, 5, 10\}$; for $p = 50$: $\nu = \{1, 5, 20\}$; and for $p = 100$: $\nu = \{1, 5, 20\}$.

For e-THPOULA, we find the best hyperparameters among the following choices: $\lambda = \{0.1, 0.05, 0.01\}$, $\epsilon = \{10^{-2}, 10^{-4}, 10^{-8}, 10^{-12}\}$, and $\beta = 10^{12}$. For SGLD, we use the following hyperparameters, $\lambda = \{0.1, 0.05, 0.01\}$ and $\beta = 10^{12}$. For ADAM and AMSGrad, the best learning rate is chosen among $\lambda = \{0.1, 0.01, 0.001\}$ with other hyperparameters $\epsilon = 10^{-8}$, $\beta_1 = 0.9$, and $\beta_2 = 0.999$ being fixed. The learning rate is decayed by 10 after 50 steps for all the optimization algorithms.

Figure 1 plots learning curves of all the optimization algorithms for different configurations of $(p, \nu)$. Table 2 shows the best test score $V_K^*(s_0)$, defined in (11), of each optimization algorithm where $V_K^*(s_0) \approx V_K(s_0)$ with $V_K(s_0)$ defined in (14). As shown in Figure 1 and Table 2, SGLD performs worst across all the experiments. On the other hand, e-THPOULA achieves similar test scores as ADAM and AMSGrad.

Following [59], we use the term “step” to indicate “epoch” (instead of “iteration”), which is a common terminology in deep learning communities.

AR(1) model. We consider the following AR(1) model:

$$R_k = \alpha + AR_{k-1} + \epsilon_k, \quad k = 0, 1, \ldots, K - 1,$$

where $\alpha \in \mathbb{R}^p$, $A \in \mathbb{R}^{p \times p}$, and $\epsilon_k \sim N_p(0, \Sigma)$, $k = 0, \ldots, K - 1$, are i.i.d. with $\Sigma \in \mathbb{R}^{p \times p}$. One observes that, in this setting, the excess returns $\{R_k\}_{k=0}^{K-1}$ are serially dependent. Thus, under the AR(1) model (15), the MDP problem (9) is reformulated as follows:

$$V_K(s_0) = \min_{g_0, \ldots, g_{K-1} \in \Omega} \mathbb{E}[-U(W_K)]$$

subject to

$$s_{k+1} = (W_k(g_k(s_k), R_k) + R_I, R_k), \quad k = 0, 1, \ldots, K - 1.$$

where $s_k := (W_k, R_{k-1})$ is the augmented state variable such that the state transition is Markovian, $d_s := p + 1$, $\eta_k := \epsilon_k$, and $m := p$.

We aim to approximate the optimization problem (16) using the deep learning approach (11). More precisely, for numerical experiments, we consider $\{R_k\}_{k=0}^{K-1}$ satisfying the AR(1) model (15) with $p = 30$, $K = 10$, $\alpha = (0.015, \ldots, 0.015) \in \mathbb{R}^p$, $R_{-1} = \frac{\alpha}{10}$, $A_{i\alpha} = -0.15$, $A_{ij} = 0$ for $i \neq j$, and $\Sigma_{ii} = 0.0238$, $\Sigma_{ij} = 0.0027$ for $i \neq j$. We fix $W_0 = 1, R_I = 1.03, \gamma = 15$ and $D = [0, 1]^p$. Moreover, the training scheme is similar to that in the case of the Black-Scholes model, but 40,000 training samples (instead of 20,000) are used for each step. For the AR(1) model (15), numerical or analytical benchmark values are not available. Therefore, we only report and compare the test scores obtained from the following four different optimization algorithms: e-TH:e POULA, SGLD, ADAM, and AMSGrad.

We use the same hyperparameters as that in the case of the Black-Scholes model for tuning the optimization algorithms, and then record the best test score among all the combinations of hyperparameters for each algorithm. Furthermore, we use three different values, i.e., 5, 20, and 50, for the number of neurons $\nu$ in the neural networks. In Figure 2, we show the test scores of the different algorithms for each value of $\nu$. The best test score is reported in Table 3, which shows that e-TH:e POULA attains the lowest scores compared to SGLD, ADAM, and AMSGrad, as desired.

3.2. Transfer learning in the multi-period portfolio optimization. This subsection discusses an interesting connection between the dynamic programming principle (DPP) and transfer learning. Moreover, in this setting, we show that our theoretical results in Theorem 4.5 and Corollary 4.6 can be applied which ensure the convergence of e-TH:e POULA (5)-(7). We consider the problem of multi-period portfolio optimization presented in Section 3.1 with slight modifications described explicitly below.
Consider the single-hidden-layer feedforward network (SLFN) $\mathcal{N} : \mathbb{R}^{d_x} \times \mathbb{R}^{d_x} \to \mathbb{R}^p$ with its $i$-th element given by

$$\mathcal{N}^i(\tilde{\theta}, z) = \tanh \left( \sum_{j=1}^{\nu} \tilde{K}_{ij}^i \sigma_1 (\langle c^j, z \rangle + \tilde{b}_j^i) \right), \quad i = 1, \ldots, p.$$  

(17)
where \( z \in \mathbb{R}^d \) is the input vector, \( \sigma \in \mathbb{R}^{k \times d} \) is the fixed (i.e. not trained) weight matrix, \( \tilde{K}_1 \in \mathbb{R}^{p \times \nu} \) is the weight parameter, \( \tilde{b}_0 \in \mathbb{R}^\nu \) is the bias parameter, \( \tilde{\theta} = ([\tilde{K}_1], \tilde{b}_0) \in \mathbb{R}^d \) is the parameter of SLFN (17) with \( \tilde{d} = \nu(p + 1) \), and \( \sigma_1(y) = \max\{0, y\}, y \in \mathbb{R} \), is the ReLU activation function. In our numerical experiments, each element in \( \tilde{c} \) is generated by a standard normal distribution. We refer to [12], [23] and [46] for the universal approximation property of neural networks with a randomly generated weight matrix. In addition, consider the set of two-hidden-layer feedforward network (TLFN) given by

\[
\mathcal{G}_\nu = \{ f : \mathbb{R}^d \to \mathbb{R}^p | f(x) = \tanh(K_3 z + b_3), z = \sigma_2(K_2 y + b_2), \}
\]

\[
y = \sigma_2(K_1 x + b_1), K_1 \in \mathbb{R}^{x \times d}, K_2 \in \mathbb{R}^{p \times \nu}, K_3 \in \mathbb{R}^{p \times \nu}, b_1, b_2 \in \mathbb{R}^\nu, b_3 \in \mathbb{R}^p \}.
\]

We note that TLFN (18) has the same structure as that of TLFN (10), however, we use here the sigmoid activation function for TLFN (18), i.e., \( \sigma_2(y) = 1/(1 + e^{-y}), y \in \mathbb{R}^\nu \), which is applied componentwise, instead of the ReLU activation function for TLFN (10).

Fix \( K > 0 \). We consider the case where the asset excess returns follow the Black-Scholes model in (13), which implies that \( \{R_k\}_{k=0}^{K-1} \) are i.i.d.. Then, consider the time-indexed optimization problem of (14):

\[
V(t, K, W_t) = \min_{g_{t_0},...,g_{k-1} \in \mathcal{U}} \mathbb{E}[\langle W_K - \gamma/2 \rangle^2 | F_t] 
\]

s.t. \( W_{k+1} = W_k(g_k(W_k), R_k) + R_f \), \( k = t, t+1, \ldots, K-1 \),

where \( t = 0, \ldots, K-1 \). We note that \( V(0, K, W_0) \) is the solution of the original problem (14), i.e., \( V(0, K, W_0) = V_K(W_0) \).

Denote by \( \Pi^*_K(\cdot) \) the neural-network-based approximated solution of the MDP problem (14) obtained using (11), where \( \Pi^N_K(\zeta; \theta) \) recursively defined in (12) is replaced with \( \Pi^N_K(\zeta; \theta) \) which is defined, for \( k = 0, 1, \ldots, K-1 \), by

\[
\Pi_{k+1} = \tilde{h}(\Pi_k, g_k(\Pi_k; \theta_k), R_k), \quad g_k(\cdot; \theta_k) \in \mathcal{G}_\nu
\]

with \( \Pi^N_K(\zeta; \theta) := \Pi_K(\zeta) := (\Pi_0, R_0, \ldots, R_{K-1}), \theta = (\theta_0, \ldots, \theta_{K-1}) \in \mathbb{R}^d \) being the parameter for the neural networks, \( d := K(\nu(d_s + \nu + p + 2) + p) \), and \( \mathcal{G}_\nu \) given in (18). This implies that

\[
V_K(\Pi_0) = V(0, K, \Pi_0) \approx \Pi^*_K(\Pi_0) = \min_{\theta} \mathbb{E}\left[ (\Pi^N_K(\zeta; \theta) - \gamma/2)^2 \right].
\]

Our aim is to compute \( V(0, K, W_0) \) using the approximated solution \( \Pi^*_K(\cdot) \), where the corresponding neural networks for \( \Pi^*_K(\cdot) \) have been already trained to approximate \( V_K(\cdot) \). This reduces our task to the training of only one SLFN (17), instead of \( K+1 \) neural networks involved in \( V(0, K+1, W_0) \) as explained in Section 3.1. As a consequence, the training time is reduced significantly as illustrated in Table 6. To justify our approach, we utilize two key ideas, i.e., DPP and the time-homogeneity property of MDP\( ^6 \), which can be described explicitly as follows:

(Dynamic programming principle) \( V(0, K, W_0) = \min_{\theta_0 \in \mathcal{U}} \mathbb{E}[V(1, K, W_1^{\theta_0})] \),

\( \text{(Time-homogeneity)} \quad V(t_1, t_2, s) = V(0, t_2 - t_1, s) \),

where \( W_1^{\theta_0} = W_0(g_0(W_0), R_0) + R_f \), and

\[
V(0, K+1, W_0) = \min_{\theta_0 \in \mathcal{U}} \mathbb{E}[V(1, K+1, W_1^{\theta_0})]
\]

\( ^6 \)See [3] and [57] for an overview of stochastic optimal control in discrete-time.
where \( W_{1}^{0}(\tilde{\theta}, W_{0}) := W_{0}(\mathfrak{M}(\tilde{\theta}, W_{0}), R_{0}) + R_{f} \) with \( \mathfrak{M} \) defined in (17). Since \( V_{K}^{*}(\cdot) \) is deterministic, our task of approximately solving the MDP problem (24) is equivalent to optimizing the parameters \( \tilde{\theta} \) of SLFN (17).

The next proposition shows that our theoretical convergence results for e-TH\( \epsilon \)-O POULA, provided in Section 4, can be applied to a regularized version of (24). More precisely, we consider the following regularized optimization problem:

\[
V(0, K + 1, W_{0}) \approx V_{K}^{*, \text{tlreg}}(W_{0}) := \min_{\tilde{\theta}} \left( E \left[ V_{K}^{*} \left( W_{1}^{0}(\tilde{\theta}, W_{0}) \right) \right] + \frac{\eta}{2(r + 1)} \| \tilde{\theta} \|^{2(r + 1)} \right)
\]

where \( r \geq 1/2 \) and \( \eta > 0 \).

**Proposition 3.1.** The optimization problem (25) satisfies Assumptions 1-4 in Section 4.

**Proof.** See Appendix A.2. \( \square \)

Thus, by using Proposition 3.1, Theorem 4.5 and Corollary 4.6 can be applied to the optimization problem (25), which provide theoretical guarantees for e-TH\( \epsilon \)-O POULA (5)-(7) to find approximate minimizers of (25). We refer to Section 4 for the precise non-asymptotic convergence bounds for e-TH\( \epsilon \)-O POULA.

**Remark 3.2.** We would like to comment on the regularization term \( \eta \| \tilde{\theta} \|^{2(r + 1)/(2(r + 1))} \), \( \tilde{\theta} \in \mathbb{R}^{d} \), added in the optimization problem (25). Theoretically, by adding this term, (part of) the stochastic gradient of the objective function (25), i.e., \( F \) defined in (63), satisfies Assumption 4. This is crucial in obtaining an upper estimate for the expected excess risk as provided in Theorem 4.5. Numerically, adding the aforementioned regularization term does not affect essentially the simulation results due to the smallness of the regularization parameter \( \eta \) (e.g., \( \eta \) is set to be \( 10^{-6} \) in the numerical experiments). This can also be seen from the numerical results in Table 4, where we obtain similar results compared to those obtained by solving the original (unregularized) problem (24) with \( \eta = 0 \).

We then compare the performance between the two training methods, i.e., full training and transfer learning. More precisely, as discussed in Section 3.1, full training refers to approximating \( V(0, K + 1, W_{0}) \) by using \( (K + 1) \) neural networks defined in (12) with the structure of each neural network specified in (10), whereas transfer learning refers to solving \( V(0, K + 1, W_{0}) \) using the approximated solution \( V_{K}^{*}(\cdot) \) as described in (20) and (21). It is worth emphasizing that the dimension \( d := \nu(p + 1) \) of the parameters in transfer learning described in (24) is significantly smaller than that of the parameters in full learning, i.e., \( d := (K + 1)(\nu(d_{s} + \nu + p + 2) + p) \).

To generate sample paths under the Black-Scholes model, in both full training and transfer learning settings, we use identical parameters as in Table 1 except that \( W_{0} \) is uniformly distributed on \([0.99, 1.01]\), i.e., \( W_{0} \sim \text{Uniform}([0.99, 1.01]) \). Then, we compute \( V(0, K + 1, W_{0}) \equiv V_{K+1}(W_{0}) \) defined in (14) with \( K = 40 \) for \( p = \{5, 50\} \) and \( K = 30 \) for \( p = 100 \). The hidden size \( \nu \) for the SLFN and TLFN is specified as follows: \( \nu = \{1, 5, 10\} \) for \( p = 5 \) and \( \nu = \{1, 5, 20\} \) for \( p = \{50, 100\} \). Moreover, we set \( r = 1 \) and \( \eta = 10^{-6} \). All the models are trained by e-TH\( \epsilon \)-O POULA with the same hyperparameters as in Section 3.1 and batch size of 128. Then, the test score is computed using 50,000 test samples. Table 4 summarizes the test scores, i.e., the approximated values \( V_{K+1}^{*}(W_{0}), V_{K}^{*, \text{tl}}(W_{0}), \) and \( V_{K}^{*, \text{tlreg}}(W_{0}) \) of \( V(0, K + 1, W_{0}) \), computed from the full training, the transfer learning, and the transfer learning with regularization, respectively, while Table 5 shows the number of parameters to be determined for each experiment. The results show that transfer learning yields a similar test score in comparison with that of full training while the dimension of parameters of the transfer learning is significantly lower than that of full training. In addition, we measure the training time for transfer learning and full training to demonstrate the computational efficiency of the former approach. Table 6 shows that the training time of transfer learning is at least three times faster than that of full learning.

3.3. **Non-linear Gamma regression.** In this subsection, we consider optimization problems involving Gamma regression models. We are interested in non-linear Gamma regression problems which extends the linear Gamma regression model by replacing its linear regressor function with a neural network in order to incorporate non-linear relations of the input variables. This approach is widely used in insurance business to predict insurance claim sizes, see, e.g., [20, 22, 52, 64].

Here, we provide an example of a non-linear Gamma regression model based on neural networks which can be used to predict a target variable \( Y \in (0, \infty) \) given an input variable \( Z \in \mathbb{R}^m \). Under the assumption that \( Y \) follows a certain Gamma distribution, its logarithmic mean function can be estimated by minimizing the negative log-likelihood (NLL) function associated with its density function [22]. We then train a neural network to approximately solve this minimization problem. More precisely, in this setting, we assume that \( Y \) follows the Gamma distribution with mean \( \mu \in (0, \infty) \) and log-dispersion \( \phi \in \mathbb{R} \). Denote by \( f_Y : (0, \infty) \to (0, \infty) \) the probability density function of \( Y \) given explicitly by

\[
 f_Y(y; \mu, \phi) = f_Y(y) := \frac{1}{y \Gamma(\exp(-\phi))} \left( \frac{y}{\mu \exp(\phi)} \right)^{\exp(-\phi)} e^{-\frac{y \exp(-\phi)}{\mu}}, \quad y \in (0, \infty),
\]

</table>

where \( \Gamma(\exp(-\phi)) \) denotes the gamma function evaluated at \( \exp(-\phi) \). Moreover, we consider the following TLFN \( \hat{\mathcal{N}} : \mathbb{R}^d \times \mathbb{R}^m \to \mathbb{R} \):

\[
\hat{\mathcal{N}}(\theta, z) := \hat{K}_3 \sigma_3 \left( \hat{K}_2 \sigma_3 \left( \hat{K}_1 z + \hat{b}_1 \right) + \hat{b}_2 \right) + \hat{b}_3, \tag{26}
\]

where \( z \in \mathbb{R}^m \) is the input vector, \( \theta = (\hat{K}_1, \hat{K}_2, \hat{K}_3, \hat{b}_1, \hat{b}_2, \hat{b}_3) \in \mathbb{R}^d \) is the parameter with \( d = d_1(m + d_2 + 1) + 2d_2 + 1, \hat{K}_1 \in \mathbb{R}^{d_1 \times m}, \hat{K}_2 \in \mathbb{R}^{d_2 \times d_1}, \hat{K}_3 \in \mathbb{R}^{1 \times d_2}, \hat{b}_1 \in \mathbb{R}^{d_1}, \hat{b}_2 \in \mathbb{R}^{d_2}, \hat{b}_3 \in \mathbb{R}, \) and \( \sigma_3(x) := \max\{0, x\} + 0.01 \min\{0, x\}, x \in \mathbb{R}, \) is the Leaky-ReLU activation function applied componentwise. Then, we model the logarithmic mean function \( \hat{\mu} : \mathbb{R}^d \times \mathbb{R}^m \to (0, \infty) \) of \( Y \) by

\[
\log \hat{\mu}(\theta, z) = \log \mathbb{E}[Y|Z = z, \theta] := \hat{\mathcal{N}}(\theta, z), \tag{27}
\]

or, equivalently, \( \hat{\mu}(\theta, z) := \exp(\hat{\mathcal{N}}(\theta, z)) \) where \( \hat{\mathcal{N}} \) is a TLFN defined in (26). Denote by \( \Theta := (\theta, \phi) \in \mathbb{R}^{d+1} \). The mean function \( \hat{\mu} \) defined in (27) can be estimated by minimizing the NLL function \( \ell : (0, \infty) \times \mathbb{R}^m \times \mathbb{R}^{d+1} \to \mathbb{R} \) given by

\[
\ell(y, z, \Theta) := -\log f_Y(y; \hat{\mu}(\theta, z), \phi) = \log y + \log \Gamma \left( \frac{1}{\exp(\phi)} \right) - \frac{1}{\exp(\phi)} \left( \log \left( \frac{y}{\exp(\phi)} \right) - \hat{\mathcal{N}}(\theta, z) \right) + \frac{y}{\exp(\phi)} \exp (-\hat{\mathcal{N}}(\theta, z)), \tag{28}
\]

see, e.g., [22], and the associated regularized optimization problem (for some \( r, \eta > 0 \)) is given as follows:

\[
\text{minimize} \quad \mathbb{R}^{d+1} \ni \Theta \mapsto u(\Theta) := \mathbb{E}[\ell(Y, Z, \Theta)] + \frac{\eta}{2(r+1)} |\theta|^{2(r+1)}. \tag{29}
\]

For the numerical experiments, we consider the auto-insurance claim data from “freMTPL2sev” in the R package “CASdatasets” [16], which contains \( N = 24,944 \) observations. Its \( i \)-th observation, \( i = 1, \ldots, N \), consists of a target variable, denoted by \( y_i \in (0, \infty) \), indicating the average claim size for one year and an input vector, denoted by \( z_i \in \mathbb{R}^m \), containing relevant quantities including, e.g., driver’s age, vehicle’s age, and region. More precisely, in this case, for each \( i \), the input vector \( z_i \in \mathbb{R}^m \) with \( m = 65 \) contains 4 continuous variables and 7 categorical variables, see Table 7 for the detailed description. We note that the dimension for each input vector \( z_i \) is 65. This is due to the fact that each categorical variable contains certain number of classes, for example, the variable “VehPower” contains 6 classes, and each element in \( z_i \) represents one class. Hence, each \( z_i \in \mathbb{R}^{65} \) contains 61 classes and 4 continuous variables as its elements.

For the training and testing purposes, we split the dataset such that the training set contains 70% of the observations and the test set contains 30% of the observations.

Table 7. Description of the attributes in each input vector.

We employ e-TH\(\varepsilon\)O POULA, SGLD defined in (8), ADAM, and AMSGrad to solve the optimization problem (28)-(29) using the aforementioned dataset. Set \(r = 0, \eta = 0.0005\). We note that the optimization problem (28)-(29) is then equivalent to an \(\ell_2\) regularized optimization problem. We search the hyperparameters for e-TH\(\varepsilon\)O POULA: \(\lambda = \{0.1, 0.01, 0.001\}\), \(\epsilon = \{10^{-2}, 10^{-4}, 10^{-8}\}\), and \(\beta = 10^{12}\). For SGLD, we use the following hyperparameters: \(\lambda = \{0.1, 0.01, 0.001, 0.0001\}\) and \(\beta = 10^{12}\). For ADAM and AMSGrad, the hyperparameters are chosen among \(\lambda = \{0.1, 0.01, 0.001\}\) where \(\epsilon = 10^{-8}\), \(\beta_1 = 0.9, \beta_2 = 0.999\) are fixed. Moreover, we decay the learning rate by 10 after 25 epochs to all the optimization algorithms. In addition, TLFN (26) with 100 neurons on each layer is trained for 50 epochs with 128 batch size. Each experiment is run three times to compute the mean and standard deviation of NLL on the test set.

Figure 3 shows the learning curves for the NLL on both the training and test set for each optimizer. Table 8 displays the mean and standard deviation of the NLL on the test set. As shown in Table 8, the performance of SGLD is significantly inferior to that of ADAM, AMSGrad, and e-TH\(\varepsilon\)O POULA, and its learning curves are highly unstable. On the contrary, ADAM, AMSGrad, and e-TH\(\varepsilon\)O POULA produce very stable learning processes. Moreover, e-TH\(\varepsilon\)O POULA achieves the lowest test NLL, implying the model trained by e-TH\(\varepsilon\)O POULA generalizes better than the models found by other optimization algorithms.

**Figure 3.** Negative likelihood curve on training and test set

4. **Non-asymptotic convergence bounds for e-TH\(\varepsilon\)O POULA**

In this section, we provide non-asymptotic error estimates for e-TH\(\varepsilon\)O POULA (5)-(7), which are established based on the assumptions provided below.
4.1. Assumptions. Let the conditions imposed in Section 2.1 be fulfilled, and let \( q \in [1, \infty), r \in [q/2, \infty) \cap \mathbb{N}, \rho \in [1, \infty) \) be fixed.

In the first assumption, we impose moment requirements for the initial value \( \theta_0 \) of e-TH\(O \) POULA (5)-(7) and for the data process \((X_n)_{n \in \mathbb{N}_0}\).

**Assumption 1.** The initial condition \( \theta_0 \) has a finite \((8r+4)\)-th moment, i.e., \( \mathbb{E}[|\theta_0|^{8r+4}] < \infty \). The process \((X_n)_{n \in \mathbb{N}_0}\) has a finite \((4r+2)\)-th moment, i.e., \( \mathbb{E}[|X_0|^{(4r+2)\rho}] < \infty \).

Recall the definition of \( G \) given in (4), which is the sum of \( G \) and \( F \). In the following assumption, we assume that \( G \) satisfies a “continuity in average” condition and a growth condition.

**Assumption 2.** There exists a constant \( L_G > 0 \) such that, for all \( \theta, \bar{\theta} \in \mathbb{R}^d \),
\[
\mathbb{E}[|G(\theta, X_0) - G(\bar{\theta}, X_0)|] \leq L_G(1 + |\theta| + |\bar{\theta}|)^{\rho-1}|\theta - \bar{\theta}|.
\]
In addition, there exists a constant \( K_G > 1 \), such that for all \( \theta \in \mathbb{R}^d \), \( x \in \mathbb{R}^m \),
\[
|G(\theta, x)| \leq K_G(1 + |x|)^{\rho}(1 + |\theta|)^{\varphi}.
\]

Then, we assume that \( F \) is locally Lipschitz continuous. Furthermore, we impose a growth condition on each component of \( F \), which enables us to obtain more relaxed step-size restrictions.

**Assumption 3.** There exists a constant \( L_F > 0 \) such that, for all \( \theta, \bar{\theta} \in \mathbb{R}^d \), \( x, \bar{x} \in \mathbb{R}^m \),
\[
|F(\theta, x) - F(\bar{\theta}, \bar{x})| \leq L_F(1 + |x| + |\bar{x}|)^{\rho-1}(1 + |\theta| + |\bar{\theta}|)^{2\rho}(|\theta - \bar{\theta}| + |x - \bar{x}|).
\]
Furthermore, there exists a constant \( K_F > 0 \) such that for all \( \theta \in \mathbb{R}^d \), \( x \in \mathbb{R}^m \), \( i = 1, \ldots, d \),
\[
|F^{(i)}(\theta, x)| \leq K_F(1 + |x|)^{\rho}(1 + |\theta|^{2\rho})(1 + |\theta|^{2\rho}).
\]

Under Assumptions 1-3, one obtains a growth condition for \( H \), and a local Lipschitz condition for \( h \). We refer to Appendix A.1 for the proofs of the statements in the following remark.

**Remark 4.1.** By Assumptions 1, 2, and 3, for any \( \theta \in \mathbb{R}^d \), \( x \in \mathbb{R}^m \), one obtains that
\[
|H(\theta, x)| \leq K_H(1 + |x|)^{\rho}(1 + |\theta|^{2\rho+1}),
\]
where \( K_H := 2^{2\rho}K_G + 3\sqrt{2d}K_F \). Moreover, by Assumptions 1, 2, and 3, we have, for any \( \theta, \bar{\theta} \in \mathbb{R}^d \),
\[
|h(\theta) - h(\bar{\theta})| \leq L_h(1 + |\theta| + |\bar{\theta}|)^{2\rho}|\theta - \bar{\theta}|,
\]
where \( L_h := \max\{L_G + L_F\mathbb{E}[(1 + 2|X_0|)^{\rho-1}], 1\} \).

Next, we impose a (local) convexity at infinity on \( F \).

**Assumption 4.** There exist Borel measurable functions \( A : \mathbb{R}^m \to \mathbb{R}^{d \times d}, B : \mathbb{R}^m \to \mathbb{R}^{d \times d} \), and \( 0 \leq \bar{r} < 2r \) such that the following holds:

(i) For any \( x \in \mathbb{R}^m, y \in \mathbb{R}^d, \langle y, A(x)y \rangle \geq 0, \quad \langle y, B(x)y \rangle \geq 0. \)

(ii) For all \( \theta, \theta' \in \mathbb{R}^d \) and \( x \in \mathbb{R}^m \),
\[
\langle \theta - \theta', F(\theta, x) - F(\theta', x) \rangle \geq (\theta - \theta', A(x)(\theta - \theta'))(|\theta|^{2\bar{r}} + |\theta'|^{2\bar{r}}) - (\theta - \theta', B(x)(\theta - \theta'))(\bar{r}|\theta|^\bar{r} + |\theta'|^\bar{r}).
\]

(iii) The smallest eigenvalue of \( \mathbb{E}[A(X_0)] \) is a positive real number \( a \), and the largest eigenvalue of \( \mathbb{E}[B(X_0)] \) is a nonnegative real number \( b \).

Under Assumptions 1-4, one can show that \( F \) and \( h \) satisfy certain dissipativity conditions. Moreover, \( h \) further satisfies a one-sided Lipschitz condition. The explicit statements are provided below, and the proofs follow the same ideas as in the proofs of [40, Remark 2.5, 2.6], which can be found in [40, Appendix 1].
Remark 4.2. By Assumptions 1, 2, 3, and 4, one obtains, for any \( \theta \in \mathbb{R}^d \), that
\[
\langle \theta, \mathbb{E}[F(\theta, X_0)] \rangle \geq a_F|\theta|^{2r+2} - b_F,
\]
where \( a_F := a/2 \) and \( b_F := (a/2 + b)R_0^{r+2} + dK^2\mathbb{E}[(1 + |X_0|)^{2r}]/(2a) \)
\[
R_F := \max\{(4b/a)^{1/(2r-\gamma)}, 2^{1/(2r)}\}.
\]
Furthermore, for any \( \theta \in \mathbb{R}^d \), we have
\[
\langle \theta, h(\theta) \rangle \geq a_h|\theta|^2 - b_h,
\]
where \( a_h := 2^9K^2\mathbb{E}[(1 + |X_0|)^{2r}], b_h := 3(2^r+1)K^2\mathbb{E}[(1 + |X_0|)^{2r}]/\min\{1, a_F\}^{r+2} + b_F \). One notes that due to [32, Eqn. (25), (26)] and [1, Theorem 2.32], (32) implies \( u \) has a minimum \( \theta^* \in \mathbb{R}^d \).

In addition, for any \( \theta, \bar{\theta} \in \mathbb{R}^d \), one obtains
\[
\langle \theta - \bar{\theta}, h(\theta) - h(\bar{\theta}) \rangle \geq -L_R|\theta - \bar{\theta}|^2,
\]
where \( L_R := L_h(1 + 2R)^{2r} > 0 \) with \( R := \max\{1, (3^{9-1}L_G/a)^{1/(2r-q+1)}, (2b/a)^{1/(2r-\gamma)}\} \).

4.2. Main results. Define, for any \( p \in \mathbb{N} \),
\[
\lambda_{p,\text{max}} := \min \left\{ 1, \frac{1}{a_F}, \frac{1}{a_F}, \min\left\{ \frac{(a_F/K F)^2}{\lambda}, \frac{(a_F/K F)^2}{\lambda}, \frac{16K^2 b^2}{(2p - 1)^2} (1 + |X_0|)^{2p} \right\} \right\}, \quad \lambda_{\text{max}} := \lambda_{4\tau + 2,\text{max}}, \quad (34)
\]
where \( a_F := a/2 \).

Our first result provides a non-asymptotic error bound in Wasserstein-1 distance between the law of e-TH\(n\) POULA (5)-(7) and \( \pi_{\beta} \).

Theorem 4.3. Let Assumptions 1, 2, 3, and 4 hold. Then, for any \( \beta > 0 \) there exist constants \( C_0, C_1, C_2 > 0 \) such that, for any \( 0 < \lambda \leq \lambda_{\text{max}} \) with \( \lambda_{\text{max}} \) given in (34), and \( n \in \mathbb{N}_0 \),
\[
W_1(\mathcal{L}(\theta_n^\lambda), \pi_{\beta}) \leq C_n e^{-C_0 n^\lambda} (\mathbb{E}[|\theta_0|^{4(2r+1)}] + 1) + C_2 \sqrt{\lambda},
\]
where \( C_0, C_1, C_2 \) are given explicitly in (52).

Then, we provide a non-asymptotic convergence result in Wasserstein-2 distance between the law of e-TH\(n\) POULA (5)-(7) and \( \pi_{\beta} \).

Corollary 4.4. Let Assumptions 1, 2, 3, and 4 hold. Then, for any \( \beta > 0 \) there exist constants \( C_3, C_4, C_5 > 0 \) such that, for any \( 0 < \lambda \leq \lambda_{\text{max}} \) with \( \lambda_{\text{max}} \) given in (34), and \( n \in \mathbb{N}_0 \),
\[
W_2(\mathcal{L}(\theta_n^\lambda), \pi_{\beta}) \leq C_4 e^{-C_5 n^\lambda} (\mathbb{E}[|\theta_0|^{4(2r+1)}] + 1)^{1/2} + C_5 \lambda^{1/4},
\]
where \( C_3, C_4, C_5 \) are given explicitly in (58).

By applying Corollary 4.4, one can obtain a non-asymptotic upper bound for the expected excess risk following the splitting approach adopted in [50].

Theorem 4.5. Let Assumptions 1, 2, 3, and 4 hold. Then, for any \( \beta > 0 \) there exist constants \( C_6, C_7, C_8, C_9 > 0 \) such that, for any \( 0 < \lambda \leq \lambda_{\text{max}} \) with \( \lambda_{\text{max}} \) given in (34), and \( n \in \mathbb{N}_0 \),
\[
\mathbb{E}[u(\theta_n^\lambda)] - u^* \leq C_7 e^{-C_6 n^\lambda} + C_8 \lambda^{1/4} + C_9 / \beta,
\]
where \( u^* := \inf_{\theta \in \mathbb{R}^d} u(\theta) \), \( C_6, C_7, C_8 \) are given explicitly in (60) while \( C_9 \) is given in (61).

Corollary 4.6. Let Assumptions 1, 2, 3, and 4 hold, and let \( C_6, C_7, C_8, \) and \( C_9 \) be defined in Theorem 4.5. For any \( \delta > 0 \), if we first choose
\[
\beta \geq \max \left\{ 1, \beta_0, \left( \frac{3d}{\delta} \log \left( L_h(1 + 4\sqrt{b_h/a_h} + \sqrt{2d/L_h})^{2r} e \right) b_h + \log \frac{64}{\delta} \right) \right\},
\]
where \( \beta_0 \) is the root of the function \( \tilde{f}(\beta) = \frac{\log(\beta + 1)}{\beta} - \frac{\delta}{36}, \beta > 0 \), i.e. \( \tilde{f}(\beta_0) = 0 \), then choose \( \lambda \leq \min\{\lambda_{\text{max}}, \delta^{4}/\{81C_8^4\}\} \), and finally choose \( n \geq \max\{1/C_6 \lambda_{\text{max}}, \log(3C_7 / \delta), (81C_8^4 / C_6 \delta^{4}) \log(3C_7 / \delta)\} \), then, we have
\[
\mathbb{E}[u(\theta_n^\lambda)] - \inf_{\theta \in \mathbb{R}^d} u(\theta) \leq \delta.
\]
5. Proofs of main theoretical results

5.1. Moment estimates. Consider the SDE \((Z_t)_{t \geq 0}\) given by

\[dZ_t = -h(Z_t)\,dt + \sqrt{2\beta^{-1}}\,dB_t,\]  

with the initial condition \(Z_0 = \theta_0\), where \((B_t)_{t \geq 0}\) is standard \(d\)-dimensional Brownian motion with its completed natural filtration denoted by \((\mathcal{F}_t)_{t \geq 0}\). We assume that \((\mathcal{F}_t)_{t \geq 0}\) is independent of \(\mathcal{G}_\infty \lor \sigma(\theta_0)\).

Under Assumptions 1, 2, 3, and 4, one notes that (35) has a unique solution adapted to \((\mathcal{F}_t)_{t \geq 0}\), due to Remark 4.2, see, e.g., [37, Theorem 1]. For any \(p \in \mathbb{N}\), the \(2p\)-th moment of SDE (35) is finite, i.e., \(\sup_{t \geq 0} \mathbb{E}[|Z_t|^{2p}] < \infty\), and its explicit upper bound can be obtained by using similar arguments as in the proof of [40, Lemma A.1]. Moreover, following the proof of [13, Proposition 1-(ii)], one can show that \(\pi_\beta\) has a finite \(2p\)-th moment, for any \(p \in \mathbb{N}\).

We introduce a time-changed version of SDE (35), which is denoted by \((Z^\lambda_t)_{t \geq 0}\) with \(Z^\lambda_0 = Z_0, t \geq 0\). For each \(\lambda > 0\), define \(B^\lambda_t := B_t/\sqrt{\lambda}\), for any \(t \geq 0\), and denote by \((\mathcal{F}^\lambda_t)_{t \geq 0} := (\mathcal{F}_t)_{t \geq 0}\) the completed natural filtration of \((B^\lambda_t)_{t \geq 0}\). One notes that \((\mathcal{F}^\lambda_t)_{t \geq 0}\) is independent of \(\mathcal{G}_\infty \lor \sigma(\theta_0)\). Then, \((Z^\lambda_t)_{t \geq 0}\) is defined explicitly by

\[dZ^\lambda_t = -\lambda h(Z^\lambda_t)\,dt + \sqrt{2\lambda\beta^{-1}}\,dB^\lambda_t,\]  

with the initial condition \(Z^\lambda_0 := \theta_0\). We will use \((Z^\lambda_t)_{t \geq 0}\) in the proofs of main theorems.

Next, we consider the continuous-time interpolation of e-TH\(_{\Theta}\) POULA (5)-(7), denoted by \((\tilde{\theta}^\lambda_t)_{t \geq 0}\), which is given by

\[d\tilde{\theta}^\lambda_t = -\lambda H(X_{\lfloor t \rfloor})\,dt + \sqrt{2\lambda\beta^{-1}}\,d\tilde{B}^\lambda_t,\]  

with the initial condition \(\tilde{\theta}^\lambda_0 := \theta_0\). One notes that the law of the process (37) coincides with the law of e-TH\(_{\Theta}\) POULA (5)-(7) at grid-points, i.e., \(\mathcal{L}(\tilde{\theta}^\lambda_t) = \mathcal{L}(\bar{\theta}^\lambda_t)\), for each \(n \in \mathbb{N}\).

For any \(p \in \mathbb{N}\), we establish \(2p\)-th moment estimates of e-TH\(_{\Theta}\) POULA (5)-(7) in the lemma below. In particular, we show that, in the special case where \(F\) depends only on \(\theta \in \mathbb{R}^d\), finite \(2p\)-th moments of e-TH\(_{\Theta}\) POULA (5)-(7) can be obtained under a more relaxed step-size restriction \(\lambda_{\max}\) given in (39) (instead of \(\lambda_{p,\max}\) given in (34)).

Lemma 5.1. Let Assumptions 1, 2, 3, and 4 hold. Then, one obtains the following:

(i) For any \(0 < \lambda \leq \lambda_{1,\max}\) with \(\lambda_{1,\max}\) given in (34), \(n \in \mathbb{N}_0\), and \(t \in (n, n + 1]\),

\[\mathbb{E}\left[|\tilde{\theta}^\lambda_t|^2\right] \leq (1 - \lambda(t - n)a_{FK}(1 - a_{FK}\lambda)^n\mathbb{E}\left[|\theta_0|^2\right] + \hat{c}_0,\]

where \(\hat{c}_0 := c_0(1 + 1/(a_{FK}))\), \(a_{FK} := a/2\), and the constants \(\kappa, c_0\) are given in (83). In particular, the above inequality implies \(\sup_{t \geq 0} \mathbb{E}\left[|\tilde{\theta}^\lambda_t|^2\right] \leq \mathbb{E}\left[|\theta_0|^2\right] + \hat{c}_0 < \infty\).

(ii) For any \(p \in [2, \infty) \cap \mathbb{N}\), \(0 < \lambda \leq \lambda_{p,\max}\) with \(\lambda_{p,\max}\) given in (34), \(n \in \mathbb{N}_0\), and \(t \in (n, n + 1]\),

\[\mathbb{E}\left[|\tilde{\theta}^\lambda_t|^{2p}\right] \leq (1 - \lambda(t - n)a_{FK}\kappa_2^2)(1 - a_{FK}\kappa_2^2)^n\mathbb{E}\left[|\theta_0|^{2p}\right] + \hat{c}_p,\]

where \(\hat{c}_p := c_p^0(1 + 1/(a_{FK}\kappa_2^2))\), \(a_{FK} := a/2\), \(\kappa_2^2 := \min\{\kappa(2), \tilde{\kappa}(2)\}\), \(c_p^0 := \max\{c_0^0(p), \hat{c}_0(p)\}\) with \(\kappa(2)\) and \(\tilde{\kappa}(2)\) and \(c_0^0(p)\) given in (108) and (127), respectively. In particular, the above result implies \(\sup_{t \geq 0} \mathbb{E}\left[|\tilde{\theta}^\lambda_t|^{2p}\right] \leq \mathbb{E}\left[|\theta_0|^{2p}\right] + \hat{c}_p < \infty\).

(iii) If there exists \(F : \mathbb{R}^d \to \mathbb{R}^d\) such that \(F(\theta, x) = F(\theta)\), for any \(\theta \in \mathbb{R}^d, x \in \mathbb{R}^m\), then (38) holds for any \(p \in [2, \infty) \cap \mathbb{N}\), \(0 < \lambda \leq \lambda_{\max}\) with \(\lambda_{\max}\) given by

\[\lambda_{\max} := \min\left\{1, \frac{1}{a_{FK}}, \frac{1}{a_{FK}}, \frac{a_{FK}^2}{16K_1^2\mathbb{E}[|(1 + |X_0|)^{2p}|]^2}\right\}.\]

Proof. See Appendix A.3. \(\Box\)

Remark 5.2. One observes that, for every \(p \in [2, \infty) \cap \mathbb{N}\), \(\lambda_{p,\max} \leq \lambda_{\max}\) with \(\lambda_{p,\max}\) and \(\lambda_{\max}\) given in (34), (39), respectively. Hence, \(\lambda_{\max}\) is indeed a relaxation of the stepsize compared to \(\lambda_{p,\max}\), \(p \in [2, \infty) \cap \mathbb{N}\). More importantly, in the case where \(F\) depends only on \(\theta\), Theorem 4.3, 4.4, and 4.5 hold for \(0 < \lambda \leq \lambda_{\max}\), which can be verified by using the same arguments as provided in Section 5.2.
For each $\bar{p} \in [2, \infty) \cap \mathbb{N}$, we denote by $V_{\bar{p}}$ the Lyapunov function given by $V_{\bar{p}}(\theta) := (1 + |\theta|^2)^{\bar{p}/2}$, for all $\theta \in \mathbb{R}^d$. Moreover, define $V_{\bar{p}}(\nu) = (1 + \nu^2)^{\bar{p}/2}$ for all $\nu \geq 0$. One notes that $V_{\bar{p}}$ is twice continuously differentiable, and possess the following properties:

$$
\sup_{\theta \in \mathbb{R}^d} (|\nabla V_{\bar{p}}(\theta)|/V_{\bar{p}}(\theta)) < \infty, \quad \lim_{|\theta| \to \infty} (|\nabla V_{\bar{p}}(\theta)|/V_{\bar{p}}(\theta)) = 0.
$$

Furthermore, we denote by $\mathcal{P}_{V_{\bar{p}}}(\mathbb{R}^d)$ the set of probability measures $\mu \in \mathcal{P}(\mathbb{R}^d)$ that satisfy the condition $\int_{\mathbb{R}^d} V_{\bar{p}}(\theta) \mu(d\theta) < \infty$.

In the following lemma, we show that the Lyapunov function $V_{\bar{p}}, \bar{p} \in [2, \infty) \cap \mathbb{N}$, satisfies a geometric drift condition.

**Lemma 5.3.** Let Assumptions 1, 2, 3, and 4 hold. Then, for any $\theta \in \mathbb{R}^d, \bar{p} \in [2, \infty) \cap \mathbb{N}$, one obtains that

$$
-(\nabla V_{\bar{p}}(\theta), h(\theta)) + \Delta V_{\bar{p}}(\theta)/\beta \leq -c_{V,1}(\bar{p}) V_{\bar{p}}(\theta) + c_{V,2}(\bar{p}),
$$

where

$$
c_{V,1}(\bar{p}) := a_h \bar{p}/4, \quad c_{V,2}(\bar{p}) := (3/4) a_h \bar{p} v_{\bar{p}}(M_V(\bar{p})) \text{ with } M_V(\bar{p}) := (1/3 + 4b_h/(3a_h) + 4 d/(3a_h \beta) + 4(\bar{p} - 2)/(3a_h \beta))^{1/2}.
$$

**Proof.** See [8, Lemma 3.5]. \hfill \Box

For every $s \geq 0$, we introduce an auxiliary process, denoted by $(t \leq s, t \geq s)$, which is crucial in establishing the convergence results. More precisely, the process $(\zeta_{s,t}^{\lambda,\nu,\lambda})_{t \geq s}$ is given by

$$
d\zeta_{s,t}^{\lambda,\nu,\lambda} = -\lambda h(t \leq s, t \geq s) dt + \sqrt{2\lambda \beta^{-1}} dB_t^\lambda,
$$

with the initial condition $\zeta_{s,t}^{\lambda,\nu,\lambda} := v \in \mathbb{R}^d$. Denote by $T \equiv T(\lambda) := [1/\lambda]$. For compact notation, for each fixed $\lambda > 0, n \in \mathbb{N}_0$, define $\tilde{\zeta}_{s,t}^{\lambda,n} := \zeta_{s,t}^{\lambda,n} = (1 + 3v_2(M_V(2)))$, and $M_V(2) := (1/3 + 4b_h/(3a_h) + 4 d/(3a_h \beta))^{1/2}$.

**Lemma 5.4.** Let Assumptions 1, 2, 3, and 4 hold. Then, one obtains the following:

(i) For any $0 < \lambda \leq \lambda_{1,\max}$ with $\lambda_{1,\max}$ given in (34), $n \in \mathbb{N}_0$, and $t \geq nT$, we have

$$
E[V_2(\tilde{\zeta}_{s,t}^{\lambda,n})] \leq e^{-\min\{a_h/2a_F \kappa\} \lambda T} E[V_2(\theta_0)] + \tilde{c}_0 + 1 + 3v_2(M_V(2)),
$$

where $\tilde{c}_0 := c_0(1 + 1/(a_F \kappa))$, the constants $c_0, \kappa$ are given in (83), and $M_V(2) := (1/3 + 4b_h/(3a_h) + 4 d/(3a_h \beta))^{1/2}$.

(ii) For any $0 < \lambda \leq \lambda_{2,\max}$ with $\lambda_{2,\max}$ given in (34), $n \in \mathbb{N}_0$, and $t \geq nT$, we have

$$
E[V_4(\tilde{\zeta}_{s,t}^{\lambda,n})] \leq e^{-\min\{a_h/2a_F \kappa\} \lambda T} E[V_4(\theta_0)] + \tilde{c}_2 + 2 + 3v_4(M_V(4)),
$$

where $\tilde{c}_2 := c_0^2(2)(1 + 1/(a_F \kappa_2)), \kappa_2 := \min\{\tilde{\kappa}(2), \tilde{\kappa}(2)\}, c_0^2(2) := \max\{\tilde{c}_0(2), \tilde{c}_0(2)\}$ with $\tilde{\kappa}(2), \tilde{c}_0(2)$ and $\tilde{\kappa}(2), \tilde{c}_0(2)$ given in (108) and (127), respectively, and where $M_V(4) := (1/3 + 4b_h/(3a_h) + 4 d/(3a_h \beta) + 8/(3a_h \beta))^{1/2}$.

**Proof.** We follow the proof of [40, Lemma 4.4] where [40, Lemma 4.2, Lemma 4.3] are replaced by Lemma 5.1, 5.3, respectively, to obtain the explicit constants. \hfill \Box

5.2. **Proofs of main theorems.** In this section, we provide a proof overview of the main theoretical results in the setting of super-linearly growing $H$ in both variables. We first introduce a semimetric $w_{1,\bar{p}}$, which is defined as follows: for any $\bar{p} \geq 1, \mu, \nu \in \mathcal{P}_{V_{\bar{p}}}(\mathbb{R}^d)$, let

$$
w_{1,\bar{p}}(\mu, \nu) := \inf_{\zeta \in \mathcal{C}(\mu, \nu)} \int_{\mathbb{R}^d} \int_{\mathbb{R}^d} [1 \wedge |\theta - \theta'|](1 + V_{\bar{p}}(\theta) + V_{\bar{p}}(\theta'))(d\theta, d\theta').
$$

The analysis of the convergence results, i.e., Theorem 4.3 and 4.4, relies on the contractivity of the Langevin SDE (35) in $w_{1,2}$, which can be deduced by using [17, Theorem 2.2]. The explicit statement of the contraction property in $w_{1,2}$, as well as the explicit contraction constants, is presented in the following lemma.
Proposition 5.5. Let Assumptions 1, 2, 3, and 4 hold. Moreover, let $\theta_0^* \in L^2$, and let $(Z_t')_{t \geq 0}$ be the solution of SDE (35) with $Z_0' := \theta_0^*$, which is independent of $\mathcal{F}_\infty := \sigma(\bigcup_{t \geq 0} \mathcal{F}_t)$. Then, one obtains
\begin{equation}
 w_{1,2}(\mathcal{L}(Z_t), \mathcal{L}(Z_t')) \leq \hat{c}_e e^{-\epsilon t} w_{1,2}(\mathcal{L}(\theta_0), \mathcal{L}(\theta_0^*)) ,
\end{equation}
where the explicit expressions for $\hat{c}, \hat{c}'$ are given below.

The contraction constant $\hat{c}$ is given by
\begin{equation}
 \hat{c} := \min \{ \hat{\phi}, c_{V,1}(2), 4c_{V,2}(2)e c_{V,1}(2) \}/2 ,
\end{equation}
where $c_{V,1}(2) := a_h/2$, $c_{V,2}(2) := 3a_hv_2(M_V(2))/2$ with $M_V(2) := (1/3+4b_h/(3a_h)+4d/(3a_h \beta))^{1/2}$, the constant $\hat{\phi}$ is given by
\begin{equation}
 \hat{\phi} := \left( \sqrt{8\pi/(\beta L_R)} \right) \exp \left( \left( c_0 \sqrt{\beta L_R/8} + \sqrt{8/(\beta L_R)} \right)^2 \right) ,
\end{equation}
and $\epsilon > 0$ is chosen such that
\begin{equation}
 \epsilon \leq 1 \wedge \left( 4c_{V,2}(2)\sqrt{2\beta \pi/L_R} \int_{0}^{\epsilon_1} \exp \left( \left( s\sqrt{\beta L_R/8} + \sqrt{8/(\beta L_R)} \right)^2 \right) ds \right)^{-1}
\end{equation}
with $\epsilon_1 := 2(4c_{V,2}(2)(1+c_{V,1}(2))/c_{V,1}(2) - 1)^{1/2}$ and $\hat{\epsilon}_1 := 2(2c_{V,2}(2)/c_{V,1}(2) - 1)^{1/2}$.

Moreover, the constant $\hat{c}'$ is given by
\begin{equation}
 \hat{c}' := (1+c_0) \exp(\beta L_R^2/8 + 2c_0)/\epsilon .
\end{equation}

Proof. One can check that [17, Theorem 2.2, Corollary 2.3] hold under Assumptions 1, 2, 3, and 4. Indeed, due to Remark 4.2, [17, Assumption 2.1] holds with $\kappa = L_R$. Then, by Lemma 5.3, [17, Assumption 2.2] holds with $V = V_2$. Finally, [17, Assumptions 2.4 and 2.5] hold due to (40). Thus, by using [17, Theorem 2.2, Corollary 2.3] and by applying the arguments in the proof of [8, Proposition 3.14], one obtains (43). To obtain the explicit constants $\hat{c}, \hat{c}'$ in (44)-(47), one may refer to the proof of [40, Proposition 4.6]. □

We proceed with the proof of Theorem 4.3. To establish a non-asymptotic upper bound in Wasserstein-1 distance between the law of $e^{-\text{THO}}$ and $\pi_\beta$ defined in (3), we apply the following splitting method: for any $n \in \mathbb{N}_0$, and $t \in (nT, (n+1)T]$,
\begin{equation}
 W_t(\mathcal{L}(\tilde{\theta}_t^\lambda), \mathcal{L}(\tilde{\theta}_t^\lambda)) \leq W_t(\mathcal{L}(\tilde{\theta}_t^\lambda), \mathcal{L}(\tilde{Z}_t^\lambda)) + W_t(\mathcal{L}(\tilde{Z}_t^\lambda), \mathcal{L}(Z_t^\lambda)) ,
\end{equation}
where $\tilde{\theta}_t^\lambda := \tilde{\theta}_t^{nT, \tilde{\theta}_t^\lambda, \lambda}$ with $\tilde{\theta}_t^{nT, \tilde{\theta}_t^\lambda, \lambda}$ defined in (41), and $Z_t^\lambda$ is defined in (36). We provide an upper bound for the first term on the RHS of (48) in the following lemma.

Lemma 5.6. Let Assumptions 1, 2, 3, and 4 hold. Then, for any $0 < \lambda \leq \lambda_{\text{max}}$ with $\lambda_{\text{max}}$ given in (34), $n \in \mathbb{N}_0$, and $t \in (nT, (n+1)T]$, one obtains
\begin{equation}
 W_2(\mathcal{L}(\tilde{\theta}_t^\lambda), \mathcal{L}(\tilde{Z}_t^\lambda)) \leq \sqrt{\lambda} \left( e^{-\min\{\hat{c}, a_F \kappa_2^\lambda, a_h\} n/4} C_0 E \left[ V_{4(2r+1)}(\theta_0) \right] + \tilde{C}_t \right)^{1/2} ,
\end{equation}
where the explicit expressions of $\kappa_2^\lambda, C_0, \tilde{C}_t$ are provided in (134).

Proof. See Appendix A.3. □

By the fact that $W_1 \leq W_{1,2}$ (see [40, Lemma A.3] for a detailed proof), and by applying Proposition 5.5, an upper estimate for the second term on the RHS of (48) can be established.

Lemma 5.7. Let Assumptions 1, 2, 3, and 4 hold. Then, for any $0 < \lambda \leq \lambda_{\text{max}}$ with $\lambda_{\text{max}}$ given in (34), $n \in \mathbb{N}_0$, and $t \in (nT, (n+1)T]$, one obtains
\begin{equation}
 W_1(\mathcal{L}(\tilde{\theta}_t^\lambda), \mathcal{L}(Z_t^\lambda)) \leq \sqrt{\lambda} \left( e^{-\min\{\hat{c}, a_F \kappa_2^\lambda, a_h\} n/4} C_2 E \left[ V_{4(2r+1)}(\theta_0) \right] + \tilde{C}_3 \right) ,
\end{equation}
where
\begin{equation}
 \tilde{C}_2 := \hat{c} e^{-\min\{\hat{c}, a_F \kappa_2^\lambda, a_h\} n/4} \left( 1 + \frac{4}{\min\{\hat{c}, a_F \kappa_2^\lambda, a_h\}} \right) \tilde{C}_2 ,
\end{equation}
and
\begin{equation}
 \tilde{C}_3 := 2(\hat{c}/\hat{c}') e^{\hat{c}'/2}(\tilde{C}_1 + 15 + 12\tilde{c}_2 + 9v_4(M_V(4)))
\end{equation}
with $\hat{c}, \hat{c}'$ given in Proposition 5.5, $C_0, \tilde{C}_1$ given in (134), and $a_F, \kappa_2^\lambda, \tilde{c}_2$ given in Lemma 5.1.
Proof. We follow exactly the proof of [40, Lemma 4.7]. More precisely, to obtain the explicit constants, we apply Proposition 5.5, Lemma 5.6, 5.1, 5.4 instead of [40, Proposition 4.6, Lemma 4.5, 4.2, 4.4]. □

One notes that $\pi_\beta$ defined in (3) is the invariant measure of (36). Then, by using Proposition 5.5, and by the fact that $W_1(\mu, \nu) \leq w_{1,2}(\mu, \nu)$, one can obtain an upper estimate for the third term on the RHS of (48), i.e., for any $0 < \lambda \leq \lambda_{\text{max}}$ with $\lambda_{\text{max}}$ given in (34), $n \in \mathbb{N}_0$, and $t \in (nT, (n + 1)T]$,

$$W_1(L(Z^\lambda_t), \pi_\beta) \leq w_{1,2}(L(Z^\lambda_0), \pi_\beta) \leq \hat{C} e^{-\lambda \lambda t} w_{1,2}(L(\theta_0), \pi_\beta). \quad (50)$$

Proof of Theorem 4.3. Recall the definition of $w_{1,2}$ in (42). By applying Lemma 5.6, 5.7 and (50) to (48), one obtains, for $t \in (nT, (n + 1)T]$,

$$W_1(L(\hat{\theta}_1^\lambda), \pi_\beta) \leq \sqrt{\lambda} \left( e^{-n_0 n^2/4} C_0 E \left[ V_4(2r+1)(\theta_0) \right] + C_1 \right)^{1/2} + \sqrt{\lambda} \left( e^{-\min\{c, a_0 n^2, a_h\} n/4} C_2 E \left[ V_4(2r+1)(\theta_0) \right] + C_3 \right) + \hat{C} e^{-\lambda \lambda t} \left( 1 + E[V_2(\theta_0)] + \int_{\mathbb{R}^d} V_2(\theta) \pi_\beta(d\theta) \right) \leq C_1 e^{-C_0 (n+1)} \left( E[|\theta_0|^{4(2r+1)}] + 1 \right) + C_2 \sqrt{\lambda}, \quad (51)$$

where

$$C_0 := \min\{\bar{c}, a_0 n^2, a_h\}/4, \quad C_1 := 2^{2r+1} e^{-\min\{c, a_0 n^2, a_h\} n/4} \left( \bar{C}_{0,1/2} + \bar{C}_2 + \hat{c} \left( 2 + \int_{\mathbb{R}^d} V_2(\theta) \pi_\beta(d\theta) \right) \right), \quad (52)$$

$$C_2 := \bar{C}_{1/2} + \bar{C}_3$$

with $\bar{c}, \hat{c}$ given in Proposition 5.5, $a_0$, $\kappa_2^\beta$ given in Lemma 5.1, $\bar{C}_0$, $\bar{C}_1$ given in (134), $\bar{C}_2$, $\bar{C}_3$ given in (49). One notes that (51) implies

$$W_1(L(\hat{\theta}_1^{\lambda n}), \pi_\beta) \leq C_1 e^{-C_0 n} \left( E[|\theta_0|^{4(2r+1)}] + 1 \right) + C_2 \sqrt{\lambda},$$

which yields the desired result by replacing $nT$ with $n$ on the LHS and by replacing $n$ with $n/T \geq \lambda n$ on the RHS.

Proof of Corollary 4.4. For any $n \in \mathbb{N}_0$, and $t \geq nT$, recall that $\zeta^\lambda_{\lambda n} := \zeta^nT, \theta^\lambda_{\lambda n}, \lambda$ with $\zeta^nT, \theta^\lambda_{\lambda n}, \lambda$ defined in (41), and that $Z^\lambda_t$ is defined in (36). To obtain a non-asymptotic estimate between the law of e-THPOULA (5)-(7) and $\pi_\beta$ (given in (3)) in Wasserstein-2 distance, we consider the following splitting approach: for any $n \in \mathbb{N}_0$, and $t \in (nT, (n + 1)T]$,

$$W_2(L(\hat{\theta}_1^\lambda), \pi_\beta) \leq W_2(L(\hat{\theta}_1^\lambda), L(\zeta^\lambda_{\lambda n})) + W_2(L(\zeta^\lambda_{\lambda n}), L(Z^\lambda_t)) + W_2(L(Z^\lambda_t), \pi_\beta). \quad (53)$$

An explicit upper estimate for the first term on the RHS of (53) is provided in Lemma 5.6. To obtain an upper bound for the second term on the RHS of (53), one follows the same lines as in the proof of [40, Lemma 4.7] while applying $W_2 \leq \sqrt{2 w_{1,2}}$ (see [40, Lemma A.3] for a detailed proof) instead of $W_1 \leq w_{1,2}$, and applying Lemma 5.1, 5.4 for the moment estimates of $\zeta_{\lambda n}$ and $\hat{\theta}_1^\lambda$ instead of [40, Lemma 4.2, 4.4]. Then, one obtains,

$$W_2(L(\zeta^\lambda_{\lambda n}), L(Z^\lambda_t)) \leq \lambda^{1/4} \left( e^{-\min\{c, a_0 n^2, a_h\} n/8} \bar{C}_4 \left( E \left[ V_4(2r+1)(\theta_0) \right] \right)^{1/2} + \bar{C}_5 \right), \quad (54)$$

where

$$\bar{C}_4 := \sqrt{\bar{c}} e^{-\min\{c, a_0 n^2, a_h\} n/8} \left( 1 + \frac{8}{\min\{c, a_0 n^2, a_h\}} \right) (\bar{c}_{0,1/2}^1 + 2 \sqrt{2}), \quad (55)$$

$$\bar{C}_5 := 4 (\sqrt{\bar{c}}/\hat{c}) e^{1/4} (\bar{C}_{1/2} + 1 + 2 \sqrt{2} + 2 \sqrt{2 \bar{c}_2} + \sqrt{3 \bar{c}_4(\gamma V(4))})$$

with $\bar{c}, \hat{c}$ given in Proposition 5.5, $\bar{C}_0$, $\bar{C}_1$ given in (134), $a_0$, $\kappa_2^\beta$, $\hat{c}_2$ given in Lemma 5.1, and $\gamma V(4)$ given in Lemma 5.3. For the last term on the RHS of (53), an upper bound can be obtained by using $W_2 \leq \sqrt{2 w_{1,2}}$ and Proposition 5.5 as follows:

$$W_2(L(Z^\lambda_t), \pi_\beta) \leq \sqrt{2 w_{1,2}^{1/2}} (L(Z^\lambda_t), \pi_\beta) \leq \sqrt{2 e^{-\lambda \lambda t/2}} w_{1,2}^{1/2} (L(\theta_0), \pi_\beta). \quad (56)$$
Applying Lemma 5.6, (54), and (56) to (53), one obtains, for any $n \in \mathbb{N}_0$, and $t \in (nT,(n+1)T]$,

$$W_2(\mathcal{L}(\hat{\theta}_t^n), \pi_\beta) \leq \sqrt{\lambda} \left( e^{-naF \lambda^2/2} c_0 \mathbb{E} \left[ V_{4(2r+1)}(\theta_0) \right] + C_1 \right)^{1/2} + \lambda^{1/4} \left( e^{-\min\{\hat{c},aF \lambda^2, a_h\} n/8} c_4 \left( \mathbb{E} \left[ V_{4(2r+1)}(\theta_0) \right] \right)^{1/2} + C_5 \right) + \sqrt{2c e^{-\lambda t/2}} \left( 1 + \mathbb{E}[V_2(\theta_0)] + \int_{\mathbb{R}^d} V_2(\theta) \pi_\beta(d\theta) \right)^{1/2},$$

where

$$C_3 := \min\{\hat{c}, aF \lambda^2, a_h\}/8,$$

$$C_4 := 2^{2r+1/2} e^{\min\{\hat{c},aF \lambda^2, a_h\}/4} \left( c_1^{1/2} + C_4 + \sqrt{2c} \left( 2 + \int_{\mathbb{R}^d} V_2(\theta) \pi_\beta(d\theta) \right)^{1/2} \right),$$

$$C_5 := \frac{C_1^{1/2}}{2} + C_5,$$

with $\hat{c}, \hat{c}$ given in Proposition 5.5, $a_F, \lambda^2$ given in Lemma 5.1, $\bar{C}_0, \bar{C}_1$ given in (134), and $C_4, \bar{C}_5$ given in (55).

By using the non-asymptotic estimate provided in Corollary 4.4, one can obtain an upper estimate for the expected excess risk, i.e., $\mathbb{E}[u(\theta_0^n)] - u^*$, where $u^* := \inf_{\theta \in \mathbb{R}^d} u(\theta)$ with $u$ given in (1). We proceed with the following splitting:

$$\mathbb{E}[u(\theta_0^n)] - u^* = \mathbb{E}[u(\theta_0^n)] - \mathbb{E}[u(Z_\infty)] + \mathbb{E}[u(Z_\infty)] - u^*, \quad \mathbb{E}[u(\theta_0^n)] - \mathbb{E}[u(Z_\infty)] \leq C_7 e^{-C_7 \lambda n} + C_8 \lambda^{1/4},$$

where

$$C_6 := C_3,$$

$$C_7 := 2^{2r} \mathbb{E}[(1 + |X_0|)^{\rho}] \left( C_4(2 + c_{2r+1} + c_{2r+1}^{1/2} + c_{Z_{\infty}}^{1/2}) + C_5 \right) \left( \mathbb{E}[\theta_0^{4(2r+1)}] \right) + 1),$$

$$C_8 := 2^{2r} \mathbb{E}[(1 + |X_0|)^{\rho}] C_5(1 + c_{2r+1} + c_{Z_{\infty}}^{1/2} + c_{2r+1}^{1/2}),$$

with $C_3, C_4, C_5$ given in (58), $c_{2r+1}$ given in Lemma 5.1, $c_{Z_{\infty}}$ denoting the $4r + 2$-th moment of $\pi_\beta$.

**Proof.** The proof follows the same arguments as in the proof of [40, Lemma 4.8]. However, to obtain explicit constants, we apply Remark 4.1 for the growth condition of $h$ rather than [40, Remark 2.2], Lemma 5.1 for the moment estimate of $\theta_0^n$ rather than [40, Lemma 4.2], and apply Corollary 4.4 for the upper estimate of $W_2(\mathcal{L}(\hat{\theta}_t^n), \pi_\beta)$ rather than [40, Corollary 2.9].

**Lemma 5.9.** Let Assumptions 1, 2, 3, and 4 hold. Then, for any $0 < \lambda \leq \lambda_{\max}$ with $\lambda_{\max}$ given in (34), $n \in \mathbb{N}_0$, and any $\beta > 0$, one obtains

$$\mathbb{E}[u(Z_\infty)] - u^* \leq C_9/\beta,$$

where

$$C_9 := \frac{d}{2} \log \left( \frac{L_{\pi}(1 + 4 \max\{\sqrt{h_0/a}, \sqrt{2d/(2L_{\pi})}\})^{2r} e\left( \frac{\beta h_0}{d} + 1 \right)}{a} \right) + \log 2.$$
**Proof of Corollary 4.6.** For any $\delta > 0$, if we first choose $\beta$ such that $C_0/\beta \leq \delta / 3$, then choose $\lambda$ such that $\lambda \leq \lambda_{\max}$ with $\lambda_{\max}$ given in (34) and $C_8 \lambda^{1/4} \leq \delta / 3$, and finally choose $C_7 e^{-C_6 \lambda n} \leq \delta / 3$, consequently, we have $E[u(\theta_n^\beta)] - u^* \leq \delta$.

We note that $C_9/\beta \leq \delta / 3$ is achieved if we choose

$$\beta \geq \max \left\{ 1, \beta_\delta, \left( \frac{3d}{\delta} \log \left( \frac{L_h(1 + 4(\sqrt{b_h/a_h} + \sqrt{2d/L_h}))^{2r_e} (b_h + 1) (d + 1)}{a_h d} \right) + \frac{\log 64}{\delta} \right) \right\},$$

where $\beta_\delta$ is the root of the function $\hat{f}(\beta) = \frac{\log(\beta + 1)}{\beta} - \frac{\delta}{3d} > 0$, i.e. $\hat{f}(\beta_\delta) = 0$. Indeed, since, for any $\beta \geq 1$,

$$\frac{C_9}{\beta} \leq \frac{d}{2\beta} \log \left( \frac{L_h(1 + 4(\sqrt{b_h/a_h} + \sqrt{2d/L_h}))^{2r_e} (b_h + 1) (d + 1)}{a_h d} \right) + \frac{\log 2}{\beta},$$

by setting $\frac{d}{2\beta} \log \left( \frac{L_h(1 + 4(\sqrt{b_h/a_h} + \sqrt{2d/L_h}))^{2r_e} (b_h + 1) (d + 1)}{a_h d} \right) + \frac{\log 2}{\beta} \leq \delta / 6$ and $\frac{d}{2\beta} \log (\beta + 1) \leq \delta / 6$, we obtain $C_0/\beta \leq \delta / 3$. Observing that, for $\beta > 0$, $\log (\beta + 1)$ is decreasing in $\beta$, yields the desired result. Furthermore, we have that $\lambda \leq \min\{\lambda_{\max}, \delta^2/(81 C_8^4)\}$, and $\lambda n \geq (1/C_0) \log(3C_7/\delta)$ which further implies that $n \geq \max\{(1/C_0 \lambda_{\max}) \log(3C_7/\delta), (81 C_8^4 / C_0 \delta^2) \log(3C_7/\delta)\}$. $\square$
A.1. Proof of auxiliary results in Section 4.1.

Proof of statement in Remark 4.1. By using Assumption 3, for any $\theta \in \mathbb{R}^d$, $x \in \mathbb{R}^m$, one obtains
\[
|F(\theta, x)| = \left( \sum_{i=1}^{d} |F^{(i)}(\theta, x)|^2 \right)^{1/2} \leq \left( \sum_{i=1}^{d} K_F^2 (1 + |x|)^{2\rho} (1 + |\theta|)^2 (1 + |\theta|^{2r}) \right)^{1/2} \leq K_F (1 + |x|)^{\rho} \sqrt{2(d + |\theta|^{2r}) (1 + |\theta|^{2r})} \leq \sqrt{2d} K_F (1 + |x|)^{\rho} (1 + |\theta|)^{1 + |\theta|^{2r}} = \sqrt{2d} K_F (1 + |x|)^{\rho} (1 + |\theta|^{2r+1}) \leq 3 \sqrt{2d} K_F (1 + |x|)^{\rho} (1 + |\theta|^{2r+1}),
\]
where the last inequality holds due to $a^v \leq 1 + a^{2r+1}$, for $v \in \{1, 2\}$, $a > 0$, $r \geq 1$. Then, by using Assumption 2, $2r \geq q \geq 1$, and $(1 + a)^{2r+1} \leq 2^{2r} (1 + a^{2r+1})$, $a > 0$, one obtains
\[
|G(\theta, x)| \leq K_G (1 + |x|)^{\rho} (1 + |\theta|)^{2r+1} \leq 2^{2r} K_G (1 + |x|)^{\rho} (1 + |\theta|^{2r+1}).
\]
Recall the expression of $H$ given in (4). Combining the results above yields the first inequality in Remark 4.1. Furthermore, one notes that the second inequality follows from the local Lipschitz continuity (in average) imposed on $F, G$, see Assumptions 1, 2, and 3.

\[\square\]

A.2. Proof of auxiliary results in Section 3.

Proof of Proposition 3.1. For illustrative purposes, we consider the case where $K = 1$. Moreover, to ease the notation, we use $W^{\eta}_{1} \mid_1$ instead of $W^{\eta}_{0} \mid_1$ throughout the proof. By using (22), (19), (23), and the fact that $\{R_k\}_{k=0}^{K-1}$ are independent, (25) can be written explicitly as
\[
V(0, 2, W_0) = \min_{g_0 \in \mathcal{U}} \mathbb{E} [V(1, 2, W^{\eta}_1)] = \min_{g_0 \in \mathcal{U}} \mathbb{E} \left[ \min_{g_1 \in \mathcal{U}} \left( W^{\eta}_2 - \frac{\gamma}{2} \right)^2 \left| F_1 \right| \right] = \min_{g_0 \in \mathcal{U}} \mathbb{E} \left[ \min_{g_1 \in \mathcal{U}} \left( W^{\eta}_1 (g_1(W^{\eta}_1), R_1) + R_f - \frac{\gamma}{2} \right)^2 \left| F_1 \right| \right] \approx \min_{g_0 \in \mathcal{U}} \mathbb{E} \left( W^{\eta}_1 (g_1(W^{\eta}_1), R_1) + R_f - \frac{\gamma}{2} \right)^2 \left| F_1 \right| = \min_{\tilde{\theta} \in \mathbb{R}^d} \nu(\tilde{\theta}),
\]
where $v$ is given by
\[
v(\tilde{\theta}) := \mathbb{E} \left( W^{\eta}_1 (g_1(W^{\eta}_1), R_1) + R_f - \frac{\gamma}{2} \right)^2 \left| F_1 \right| = \min_{\tilde{\theta} \in \mathbb{R}^d} \nu(\tilde{\theta}),
\]
and where we recall that $W^{\eta}_1 = W_0(\Theta(\tilde{\theta}, W_0), R_0) + R_f \in \mathbb{R}$ with $\Theta$ given in (17), $g_1$ denotes the approximation of the optimal $g_1$ by the neural network defined in (18) with trained parameters.
\[ \theta^* = (\theta_0^*, \ldots, \theta_{K-1}^*) , \quad \overline{r}_1 \in \mathbb{R}^{p \times p} \text{ with } \overline{r}_1^{ij} := \mathbb{E}[(R_1)^2] \text{ and } \overline{r}_1^{ij} := \mathbb{E}[R_1^i R_1^j] \text{ for } i \neq j, \overline{r}_1 \in \mathbb{R}^p \text{ with } r_1^i := \mathbb{E}[R_1^i], \gamma > 0, r \geq 1/2, \text{ and } \eta > 0. \] In particular, \( \bar{g}_i(y) := \tanh(K_1^i y + \bar{b}_1^i) + b_1^i, y \in \mathbb{R}, \) where \( \sigma_2(z) = 1/(1 + e^{-z}), z \in \mathbb{R}, \) is the sigmoid activation function applied componentwise, and \( \theta^* = ([K_1^1], [K_2^1], [K_3^1], b_1^1, b_2^1, b_3^1) \) are the trained parameters. For any \( \tilde{\theta} \in \mathbb{R}^d, z \in \mathbb{R}, r_0 \in \mathbb{R}^p, \) denote by

\[ w_1^0 := z(9n(\tilde{\theta}, z), r_0) + R_f). \]

Then, the stochastic gradient \( H : \mathbb{R}^d \times \mathbb{R}^m \to \mathbb{R}^p \) of \( v \) defined in (62) is of the form \( H(\tilde{\theta}, x) := G(\tilde{\theta}, x) + F(\tilde{\theta}, x) \) for all \( \tilde{\theta} \in \mathbb{R}^d \) and all \( x \in \mathbb{R}^m, \) \( m = p + 1, \) with \( x = (r_0, z), \) \( r_0 = (r_0^1, \ldots, r_0^p) \in \mathbb{R}^p, z \in \mathbb{R}, \) where the functions \( F \) and \( G \) are given by

\[ F(\tilde{\theta}, x) := \eta \partial \tilde{\theta} \eta^{2r}, \quad G(\tilde{\theta}, x) := \left( G_{K_1^1}(\tilde{\theta}, x), \ldots, G_{K_p^p}(\tilde{\theta}, x), G_{b_1^1}(\tilde{\theta}, x), \ldots, G_{b_\nu}(\tilde{\theta}, x) \right), \quad (63) \]

where for \( I = 1, \ldots, p, J = 1, \ldots, \nu, \)

\[
G_{K_1^J}(\tilde{\theta}, x) := 2w_1^0 \partial_{K_1^J} w_1^0 \left( p \sum_{i=1}^{p} (\bar{g}_i^1(w_1^0)^2)\overline{r}_1^{ij} + \sum_{i \neq j}^{p} \bar{g}_i^1(w_1^0) \bar{g}_j^1(w_1^0) \overline{r}_1^{ij} + 2 \sum_{i=1}^{p} \bar{g}_i^1(w_1^0) \overline{r}_1^{ij} R_f + R_f^2 \right)
+ (w_1^0)^2 \left( \sum_{i=1}^{p} \bar{g}_i^1(w_1^0) \partial_{K_1^J} \bar{g}_i^1(w_1^0) \overline{r}_1^{ij} + \sum_{i \neq j}^{p} \partial_{K_1^J} \bar{g}_i^1(w_1^0) \bar{g}_j^1(w_1^0) \overline{r}_1^{ij} \right)
+ \sum_{i \neq j}^{p} \bar{g}_i^1(w_1^0) \partial_{K_1^J} \bar{g}_j^1(w_1^0) \overline{r}_1^{ij} + 2 \sum_{i=1}^{p} \partial_{K_1^J} \bar{g}_i^1(w_1^0) \overline{r}_1^{ij} R_f \right)
- \left( \partial_{K_1^J} w_1^0 \gamma \left( \sum_{i=1}^{p} \bar{g}_i^1(w_1^0) \overline{r}_1^{ij} + R_f \right) + w_1^0 \gamma \sum_{i=1}^{p} \partial_{K_1^J} \bar{g}_i^1(w_1^0) \overline{r}_1^{ij} \right),
\]

\[
G_{b_0^J}(\tilde{\theta}, x) := 2w_1^0 \partial_{b_0^J} w_1^0 \left( p \sum_{i=1}^{p} (\bar{g}_i^1(w_1^0)^2)\overline{r}_1^{ij} + \sum_{i \neq j}^{p} \bar{g}_i^1(w_1^0) \bar{g}_j^1(w_1^0) \overline{r}_1^{ij} + 2 \sum_{i=1}^{p} \bar{g}_i^1(w_1^0) \overline{r}_1^{ij} R_f + R_f^2 \right)
+ (w_1^0)^2 \left( \sum_{i=1}^{p} \bar{g}_i^1(w_1^0) \partial_{b_0^J} \bar{g}_i^1(w_1^0) \overline{r}_1^{ij} + \sum_{i \neq j}^{p} \partial_{b_0^J} \bar{g}_i^1(w_1^0) \bar{g}_j^1(w_1^0) \overline{r}_1^{ij} \right)
+ \sum_{i \neq j}^{p} \bar{g}_i^1(w_1^0) \partial_{b_0^J} \bar{g}_j^1(w_1^0) \overline{r}_1^{ij} + 2 \sum_{i=1}^{p} \partial_{b_0^J} \bar{g}_i^1(w_1^0) \overline{r}_1^{ij} R_f \right)
- \left( \partial_{b_0^J} w_1^0 \gamma \left( \sum_{i=1}^{p} \bar{g}_i^1(w_1^0) \overline{r}_1^{ij} + R_f \right) + w_1^0 \gamma \sum_{i=1}^{p} \partial_{b_0^J} \bar{g}_i^1(w_1^0) \overline{r}_1^{ij} \right),
\]

and where

\[
\partial_{K_1^J} w_1^0 := z r_0 \sech \left( \nu \sum_{j=1}^{p} \overline{K}_1^J \sigma(c^j z + \tilde{b}_0^j) \right) \left(c^j z + \tilde{b}_0^j\right) \mathbb{1}_{A_j}(z), \quad \partial_{K_1^J} \bar{g}_i^1(w_1^0) := \bar{g}_i^1(w_1^0) \partial_{K_1^J} w_1^0
\]

\[
\partial_{b_0^J} w_1^0 := z \sum_{j=1}^{p} \sech \left( \nu \sum_{j=1}^{p} \overline{K}_1^J \sigma(c^j z + \tilde{b}_0^j) \right) \overline{R}_0 \overline{K}_1^J \mathbb{1}_{A_j}(z), \quad \partial_{b_0^J} w_1^0 := \bar{g}_i^1 w_1^0 \partial_{b_0^J} w_1^0
\]

(64)
with
\[ A_j := \{ z \in \mathbb{R} | e^j z + \tilde{b}^j_0 \geq 0 \}, \] (66)
and \( \tilde{g}_i'(w_1^{\alpha}) \) denoting the derivative of \( \tilde{g}_i(y) \) w.r.t. \( y \) composed with \( w_1^{\alpha} \). Then, by using [40, Proposition 3.1], one can show that (25) satisfies Assumptions 1-4, and thus Theorem 4.3, Corollary 4.4, and Theorem 4.5 can be applied to the optimization problem (25). Indeed, we first note that the conditions imposed on \( x := (r_0, z) \in \mathbb{R}^m \) in [40, Proposition 3.1] can be satisfied for a wide range of distributions. For example, \( X := (R_0, Z) \) with \( R_0 \) and \( Z \) being independent, \( R_0 \) following a (three-parameter) log-normal distribution (see [56]), and \( Z \) following a uniform distribution is one of the valid choices which is used in our numerical experiments. Furthermore, the stochastic gradient of \( v \) defined in (62) are given explicitly in (63)-(66), which has a similar form as that specified in [40, Proposition 3.1 (20)-(21)]. By setting \( q = 2, r = 1, \rho = 7 \), following the same arguments as in the proof of [40, Proposition 3.1] yields the desired result.

\[ \square \]

A.3. Proof of auxiliary results in Section 5.

Lemma A.1. Let Assumption 3 hold. Then, for any \( \theta \in \mathbb{R}^d \), \( x \in \mathbb{R}^m \), \( 0 < \lambda \leq 1 \), \( i = 1, \ldots, d \), one obtains the following estimates for \( G^{(i)}_\lambda \) and \( F^{(i)}_\lambda \) given in (7):

\[ |G^{(i)}_\lambda(\theta, x)| \leq 2\lambda^{-1/2}, \]
\[ |F^{(i)}_\lambda(\theta, x)| \leq \lambda^{-1/2}(1 + |x|)^\rho \left( K_F + K_F|\theta^{(i)}| \right). \] (67)

Proof. For any \( \theta \in \mathbb{R}^d \), \( x \in \mathbb{R}^m \), \( 0 < \lambda \leq 1 \), \( i = 1, \ldots, d \), by using the expression of \( G^{(i)}_\lambda(\theta, x) \) given in (7), one obtains,

\[ |G^{(i)}_\lambda(\theta, x)| = \frac{G^{(i)}(\theta, x)}{1 + \sqrt{\lambda}|G^{(i)}(\theta, x)|} \left( 1 + \frac{\sqrt{\lambda}}{\varepsilon + |G^{(i)}(\theta, x)|} \right) \leq \lambda^{-1/2}\sqrt{\lambda}|G^{(i)}(\theta, x)| + \frac{\sqrt{\lambda}}{1 + \sqrt{\lambda}|G^{(i)}(\theta, x)|}(1 + |G^{(i)}(\theta, x)|), \]
\[ \leq 2\lambda^{-1/2}. \]

Furthermore, by using the expression of \( F^{(i)}_\lambda \) given in (7) and Assumption 3, one obtains

\[ |F^{(i)}_\lambda(\theta, x)| = \frac{F^{(i)}(\theta, x)}{1 + \sqrt{\lambda}|\theta|^{2r}} \leq \lambda^{-1/2}\sqrt{\lambda}K_F(1 + |x|)^\rho(1 + |\theta^{(i)}|)(1 + |\theta|^{2r}) \]
\[ \leq \lambda^{-1/2}K_F(1 + |x|)^\rho(1 + |\theta^{(i)}|)(\sqrt{\lambda} + \sqrt{\lambda}|\theta|^{2r}) \]
\[ \leq \lambda^{-1/2}(1 + |x|)^\rho \left( K_F + K_F|\theta^{(i)}| \right). \]

This completes the proof. \( \square \)

Proof of Lemma 5.1-(i). The following inequality will be applied throughout the proof: for any \( z \geq 1 \), \( l \in \mathbb{N} \), \( a_i \geq 0 \), \( i = 1, \ldots, l \),

\[ \left( \sum_{i=1}^{l} a_i \right)^z \leq l^{z-1} \sum_{i=1}^{l} a_i^z. \] (68)

Recall the continuous-time interpolation of e-TH=O POULa given in (37). Throughout the proof, let \( 0 < \lambda \leq \lambda_{1,\max} \) with \( \lambda_{1,\max} \) defined in (34), \( n \in \mathbb{N}_0 \), and \( t \in (n, n+1] \). We denote by

\[ \Delta_{n,t}^\lambda := \tilde{A}^\lambda_n - \lambda H\lambda(\tilde{A}^\lambda_n, X_{n+1})(t - n), \]
\[ \Xi_{n,t}^\lambda := \sqrt{2\lambda^2}(B_t^\lambda - B_{n}^\lambda). \] (69)

Then, one observes that

\[ \mathbb{E}\left[ |\tilde{A}^\lambda_n|^{2 \rho} \right] = \mathbb{E}\left[ |\Delta_{n,t}^\lambda|^{2 \rho} \right] + 2\lambda(t - n)d/\beta. \] (70)
To obtain an upper bound for the first term on the RHS of (70), note first that by (69),
\[
|\Delta_{n,t}^\lambda|^2 = |\overline{\theta}_n|^2 - 2\lambda(t - n) \left( \overline{\theta}_n, H_\lambda (\overline{\theta}_n, X_{n+1}) \right) + \lambda^2(t - n)^2 |H_\lambda(\overline{\theta}_n, X_{n+1})|^2.
\] (71)

One further calculates, by using (6), (7), \(0 < \lambda \leq \lambda_{1,\text{max}} \leq 1\), that
\[
- \left\langle \overline{\theta}_n^\lambda, H_\lambda (\overline{\theta}_n, X_{n+1}) \right\rangle = -\sum_{i=1}^d \overline{\theta}_n^{\lambda,(i)} \left( F_i^{(i)}(\overline{\theta}_n, X_{n+1}) + G_i^{(i)}(\overline{\theta}_n, X_{n+1}) \right)
\]
\[
= -\sum_{i=1}^d \overline{\theta}_n^{\lambda,(i)} \left( F_i^{(i)}(\overline{\theta}_n, X_{n+1}) - \sum_{i=1}^d \overline{\theta}_n^{\lambda,(i)} G_i^{(i)}(\overline{\theta}_n, X_{n+1}) \right)
\]
\[
\leq -\frac{\langle \overline{\theta}_n^\lambda, F(\overline{\theta}_n, X_{n+1}) \rangle}{1 + \sqrt{\lambda}|\overline{\theta}_n|^2r} + \sum_{i=1}^d \frac{|\overline{\theta}_n^{\lambda,(i)}|^2 |G_i^{(i)}(\overline{\theta}_n, X_{n+1})| (1 + \sqrt{\lambda}|\overline{\theta}_n|^2r)}{(1 + \sqrt{\lambda}|G_i^{(i)}(\overline{\theta}_n, X_{n+1})|)(1 + \sqrt{\lambda}|\overline{\theta}_n|^2r)} + d|\overline{\theta}_n|^4.
\]

Then, by using Assumption 2, one obtains
\[
- \left\langle \overline{\theta}_n^\lambda, H_\lambda (\overline{\theta}_n, X_{n+1}) \right\rangle \leq -\frac{\langle \overline{\theta}_n^\lambda, F(\overline{\theta}_n, X_{n+1}) \rangle}{1 + \sqrt{\lambda}|\overline{\theta}_n|^2r} + \frac{dK_G(1 + |X_{n+1}|)^{\rho} + |\overline{\theta}_n|^4}{1 + \sqrt{\lambda}|\overline{\theta}_n|^2r}.
\] (72)

which, by using \(1 \leq q \leq 2r\), and (68) (with \(l \leftarrow 2, z \leftarrow 2r + 1\)), yields
\[
- \left\langle \overline{\theta}_n^\lambda, H_\lambda (\overline{\theta}_n, X_{n+1}) \right\rangle \leq -\frac{\langle \overline{\theta}_n^\lambda, F(\overline{\theta}_n, X_{n+1}) \rangle}{1 + \sqrt{\lambda}|\overline{\theta}_n|^2r} + \frac{2^{2r}dK_G(1 + |X_{n+1}|)^{\rho} + |\overline{\theta}_n|^4}{1 + \sqrt{\lambda}|\overline{\theta}_n|^2r}.
\] (73)

Furthermore, one notes that, by using (6), Lemma A.1, and (68) (with \(l \leftarrow 3, z \leftarrow 2\)),
\[
|H_\lambda(\overline{\theta}_n, X_{n+1})|^2 = |G_\lambda(\overline{\theta}_n, X_{n+1})|^2 + 2\left( G_\lambda(\overline{\theta}_n, X_{n+1}), F_\lambda(\overline{\theta}_n, X_{n+1}) \right) + |F_\lambda(\overline{\theta}_n, X_{n+1})|^2
\]
\[
\leq 4d\lambda^{-1} + 4d\lambda^{-1}(1 + |X_{n+1}|)^{\rho}(K_F + K_F^\lambda(\overline{\theta}_n)^4)
\]
\[
+ \lambda^{-1}(1 + |X_{n+1}|)^{2\rho} \sum_{i=1}^d \left( K_F + K_F(\overline{\theta}_n^{\lambda,(i)}) + \sqrt{\lambda}K_F(\overline{\theta}_n^{\lambda,(i)}) |\overline{\theta}_n|^2r \right)^2
\]
\[
\leq d\lambda^{-1}(1 + 4(1 + |X_{n+1}|)^{\rho} K_F) + 4d\lambda^{-1}(1 + |X_{n+1}|)^{\rho} K_F(\overline{\theta}_n)^4
\]
\[
+ 3d\lambda^{-1}(1 + |X_{n+1}|)^{2\rho} K_F^2 + \frac{3(1 + |X_{n+1}|)^{2\rho} K_F^2 |\overline{\theta}_n|^4}{1 + \sqrt{\lambda}|\overline{\theta}_n|^{2r})^2.
\] (73)

Substituting (72), (73) into (71) yields
\[
|\Delta_{n,t}^\lambda|^2 \leq |\overline{\theta}_n|^2 - \frac{2\lambda(t - n)(\overline{\theta}_n, F(\overline{\theta}_n, X_{n+1}))}{1 + \sqrt{\lambda}|\overline{\theta}_n|^2r} + 2\lambda(t - n)d^{2r} K_G(1 + |X_{n+1}|)^{\rho}
\]
\[
+ 2\lambda(t - n)d|\overline{\theta}_n|^4 + \frac{2\lambda(t - n)d(2^{2r} K_G(1 + |X_{n+1}|)^{\rho} + 1) |\overline{\theta}_n|^{2r+1}}{1 + \sqrt{\lambda}|\overline{\theta}_n|^2r}
\]
\[
+ \lambda(t - n)^2d(4 + 4(1 + |X_{n+1}|)^{\rho} K_F + 3(1 + |X_{n+1}|)^{2\rho} K_F^2)
\]
\[
+ 4\lambda(t - n)^2(1 + |X_{n+1}|)^{2\rho} K_F^2 |\overline{\theta}_n|^{4r+2}
\]
\[
+ \frac{3(1 + |X_{n+1}|)^{2\rho} K_F^2 |\overline{\theta}_n|^4}{1 + \sqrt{\lambda}|\overline{\theta}_n|^{2r})^2}.
\]
\[ \begin{align*}
& \leq \left| \tilde{\theta}_n \right|^2 - \frac{2\lambda(t - n) \langle \tilde{\theta}_n, F(\tilde{\theta}_n, X_{n+1}) \rangle}{1 + \sqrt{\lambda} |\tilde{\theta}_n|^{2\tau}} \\
& \quad + \lambda(t - n)d(1 + |X_{n+1}|)^{2\rho}(2^{2\tau+1}K_G + 4 + 4KF + 3K_F^r) \\
& \quad + 4\lambda(t - n)d(1 + |X_{n+1}|)^{\rho}(1 + K_F)|\tilde{\theta}_n| \\
& \quad + \frac{2\lambda(t - n)d(2^{2\tau}K_G(1 + |X_{n+1}|)^{\rho} + 1)|\tilde{\theta}_n|^{2\tau+1}}{1 + \sqrt{\lambda} |\tilde{\theta}_n|^{2\tau}} \\
& \quad + \frac{3\lambda(t - n)(1 + |X_{n+1}|)^{2\rho}K_F^2(1 + |\tilde{\theta}_n|^{2\tau+1})}{1 + \sqrt{\lambda} |\tilde{\theta}_n|^{2\tau}} \\
& \quad + \frac{3\lambda^2(t - n)^2(1 + |X_{n+1}|)^{2\rho}K_F^2|\tilde{\theta}_n|^{4\tau+2}}{(1 + \sqrt{\lambda} |\tilde{\theta}_n|^{2\tau})^2},
\end{align*} \]

where the last inequality holds due to \(0 < t - n \leq 1\) and \(a^2 \leq 1 + a^{2\tau+1}\), for \(a \geq 0\). Moreover, one observes that, for any \(\theta \in \mathbb{R}^d\),

\[ |\theta| = \frac{|\theta|(1 + \sqrt{\lambda} |\theta|^{2\tau})}{1 + \sqrt{\lambda} |\theta|^{2\tau}} \leq \frac{|\theta| + |\theta|^{2\tau+1}}{1 + \sqrt{\lambda} |\theta|^{2\tau}} \leq 1 + \frac{2|\theta|^{2\tau+1}}{1 + \sqrt{\lambda} |\theta|^{2\tau}}. \]

Applying (75) to (74) and using \(0 < t - n \leq 1\) yield,

\[ \begin{align*}
|\Delta_{n,t}^\lambda|^2 & \leq \left| \tilde{\theta}_n \right|^2 - \frac{2\lambda(t - n)\langle \tilde{\theta}_n, F(\tilde{\theta}_n, X_{n+1}) \rangle}{1 + \sqrt{\lambda} |\tilde{\theta}_n|^{2\tau}} \\
& \quad + \lambda(t - n)d(1 + |X_{n+1}|)^{2\rho}(2^{2\tau+1}K_G + 8 + 8KF + 6K_F^r) \\
& \quad + \frac{\lambda(t - n)d(1 + |X_{n+1}|)^{2\rho}(2^{2\tau+1}K_G + 10 + 8KF + 3K_F^r)|\tilde{\theta}_n|^{2\tau+1}}{1 + \sqrt{\lambda} |\tilde{\theta}_n|^{2\tau}} \\
& \quad + \frac{3\lambda^2(t - n)^2(1 + |X_{n+1}|)^{2\rho}K_F^2|\tilde{\theta}_n|^{4\tau+2}}{(1 + \sqrt{\lambda} |\tilde{\theta}_n|^{2\tau})^2}.
\end{align*} \]

By taking conditional expectation on both sides, by using Remark 4.2, and by the fact that \(X_{n+1}\) is independent of \(\tilde{\theta}_n\), the above result yields,

\[ \begin{align*}
\mathbb{E} \left[ |\Delta_{n,t}^\lambda|^2 \right| \tilde{\theta}_n & \leq \left| \tilde{\theta}_n \right|^2 - \frac{2\lambda(t - n)a_F|\tilde{\theta}_n|^{2\tau+2}}{1 + \sqrt{\lambda} |\tilde{\theta}_n|^{2\tau}} \\
& \quad + \lambda(t - n)d\mathbb{E}((1 + |X_0|)^{2\rho})(2b_F + 2^{2\tau+1}K_G + 8 + 8KF + 6K_F^r) \\
& \quad + \frac{\lambda(t - n)d\mathbb{E}((1 + |X_0|)^{2\rho})(2^{2\tau+1}K_G + 10 + 8KF + 3K_F^r)|\tilde{\theta}_n|^{2\tau+1}}{1 + \sqrt{\lambda} |\tilde{\theta}_n|^{2\tau}} \\
& \quad + \frac{3\lambda^2(t - n)^2\mathbb{E}[(1 + |X_0|)^{2\rho}K_F^2|\tilde{\theta}_n|^{4\tau+2}}{(1 + \sqrt{\lambda} |\tilde{\theta}_n|^{2\tau})^2}.
\end{align*} \]

where for any \(\theta \in \mathbb{R}^d \setminus \{(0, \ldots, 0)\},

\[ T_1(\theta) := \frac{1}{|\theta|^2} \left( \frac{a_F |\theta|^{2\tau+2}}{1 + \sqrt{\lambda} |\theta|^{2\tau}} - \frac{\mathbb{E}((1 + |X_0|)^{2\rho})(2^{2\tau+1}K_G + 10 + 8KF + 3K_F^r)|\theta|^{2\tau+1}}{1 + \sqrt{\lambda} |\theta|^{2\tau}} \right), \]

and for any \(\theta \in \mathbb{R}^d, \)

\[ T_2(\theta) := \frac{a_F |\theta|^{2\tau+2}}{1 + \sqrt{\lambda} |\theta|^{2\tau}} - \frac{3\lambda\mathbb{E}[(1 + |X_0|)^{2\rho}K_F^2|\theta|^{4\tau+2}}{(1 + \sqrt{\lambda} |\theta|^{2\tau})^2}. \]

One observes that,

\[ \frac{a_F |\theta|^{2\tau+2}}{1 + \sqrt{\lambda} |\theta|^{2\tau}} - \frac{\mathbb{E}((1 + |X_0|)^{2\rho})(2^{2\tau+1}K_G + 10 + 8KF + 3K_F^r)|\theta|^{2\tau+1}}{1 + \sqrt{\lambda} |\theta|^{2\tau}} > \frac{a_F |\theta|^{2\tau+2}}{2(1 + \sqrt{\lambda} |\theta|^{2\tau})}. \]
\[ \Rightarrow |\theta| > \frac{2d\mathbb{E}|(1 + |X_0|)^{2\rho}|(2^{2r+1}K_G + 10 + 8K_F + 3K_F^2)}{a_F}. \]

Denote by \( M_0 := 2d\mathbb{E}|(1 + |X_0|)^{2\rho}|(2^{2r+1}K_G + 10 + 8K_F + 3K_F^2)/\min\{1, a_F\}. \) The above calculation and the fact that \( f(s) := s/(1 + \sqrt{\lambda}s) \) is non-decreasing for all \( s \geq 0 \) imply that, for any \( |\theta| > M_0, \)

\[ T_1(\theta) > \frac{a_F|\theta|^{2r}}{2(1 + \sqrt{\lambda}|\theta|^{2r})} > \frac{a_FM_0^{2r}}{2(1 + \sqrt{\lambda}M_0^{2r})} \geq a_F\kappa, \]  \( \text{(78)} \)

where \( \kappa := M_0^{2r}/(2(1 + M_0^{2r})). \) In addition, for any \( \theta \in \mathbb{R}^d, \) one notes that

\[ T_2(\theta) = \frac{a_F|\theta|^{2r+2} + \sqrt{\lambda}a_F|\theta|^{4r+2} - 3\mathbb{E}|(1 + |X_0|)^{2\rho}|K_1^2|\theta|^{4r+2}}{(1 + \sqrt{\lambda}|\theta|^{2r})^2} \geq \frac{\sqrt{\lambda}a_F|\theta|^{4r+2} - 3\mathbb{E}|(1 + |X_0|)^{2\rho}|K_1^2|\theta|^{4r+2}}{(1 + \sqrt{\lambda}|\theta|^{2r})^2}. \]

Moreover, it holds that, for any \( \theta \in \mathbb{R}^d, \)

\[ \frac{\sqrt{\lambda}a_F|\theta|^{4r+2} - 3\mathbb{E}|(1 + |X_0|)^{2\rho}|K_1^2|\theta|^{4r+2}}{(1 + \sqrt{\lambda}|\theta|^{2r})^2} \geq 0 \Leftrightarrow \lambda \leq \frac{a_F^2}{9(\mathbb{E}|(1 + |X_0|)^{2\rho}|)K_1^4}. \]

which is satisfied automatically since \( 0 < \lambda \leq \lambda_{1,\text{max}} \leq a_F^2/(9(\mathbb{E}|(1 + |X_0|)^{2\rho}|)K_1^4) \) by the definition of \( \lambda_{1,\text{max}} \) in (34). Therefore, we obtain that

\[ T_2(\theta) \geq 0. \]  \( \text{(79)} \)

Denote by \( S_{n,M_0} := \{ \omega \in \Omega : |\hat{\theta}_n^\lambda(\omega)| > M_0 \}. \) Then, by using (77), (78), (79), we have that

\[ \mathbb{E}\left[ |\Delta_n^{\lambda}|^2 \mathbb{1}_{S_{n,M_0}} \right] \leq (1 - \lambda(t - n)a_F\kappa)|\hat{\theta}_n^\lambda|^2 \mathbb{1}_{S_{n,M_0}} + \lambda(t - n)c_1 \mathbb{1}_{S_{n,M_0}}, \]  \( \text{(80)} \)

where \( c_1 := d\mathbb{E}[(1 + |X_0|)^{2\rho}](2b_F + 2^{2r+1}K_G + 8 + 8K_F + 6K_F^2). \) Moreover, by using (77), the expression of \( T_1(\theta) \) for \( \theta \in \mathbb{R}^d \setminus \{0, \ldots, 0\}, \) and (79), one notes that

\[ \mathbb{E}\left[ |\Delta_n^{\lambda}|^2 \mathbb{1}_{S_{n,M_0}} \right] \leq (1 - \lambda(t - n)a_F\kappa)|\hat{\theta}_n^\lambda|^2 \mathbb{1}_{S_{n,M_0}} + \lambda(t - n)c_1 \mathbb{1}_{S_{n,M_0}} + \lambda(t - n)\left( a_F\kappa M_0^2 + d\mathbb{E}[(1 + |X_0|)^{2\rho}](2^{2r+1}K_G + 10 + 8K_F + 3K_F^2)M_0^{2r+1} \right) \mathbb{1}_{S_{n,M_0}}. \]  \( \text{(81)} \)

By using (80), (81), one obtains that

\[ \mathbb{E}\left[ |\Delta_n^{\lambda}|^2 \mathbb{1}_{S_{n,M_0}} \right] \leq (1 - \lambda(t - n)a_F\kappa)|\hat{\theta}_n^\lambda|^2 + \lambda(t - n)c_2, \]  \( \text{(82)} \)

where \( c_2 := c_1 + a_F\kappa M_0^2 + d\mathbb{E}[(1 + |X_0|)^{2\rho}](2^{2r+1}K_G + 10 + 8K_F + 3K_F^2)M_0^{2r+1}. \)

Substituting (82) into (70) yields

\[ \mathbb{E}\left[ |\hat{\theta}_n^\lambda|^2 \right] = (1 - \lambda(t - n)a_F\kappa)|\hat{\theta}_n^\lambda|^2 + \lambda(t - n)c_3, \]

where \( \kappa := M_0^{2r}/(2(1 + M_0^{2r})), \)

\[ M_0 := 2d\mathbb{E}[(1 + |X_0|)^{2\rho}](2^{2r+1}K_G + 10 + 8K_F + 3K_F^2)/\min\{1, a_F\}, \]

\[ c_0 := 2d/\beta + d\mathbb{E}[(1 + |X_0|)^{2\rho}](2b_F + 2^{2r+1}K_G + 8 + 8K_F + 6K_F^2) \]

\[ + a_F\kappa M_0^2 + d\mathbb{E}[(1 + |X_0|)^{2\rho}](2^{2r+1}K_G + 10 + 8K_F + 3K_F^2)M_0^{2r+1}. \]  \( \text{(83)} \)
One concludes that
\[
\mathbb{E} \left[ |\tilde{\theta}_n|^2 \right] &= \mathbb{E} \left[ |\tilde{\theta}^p_n|^2 | \tilde{\theta}_n^\lambda \right]
\leq (1 - \lambda(t - n)a_{\mathcal{F}K})\mathbb{E} \left[ |\tilde{\theta}_n^\lambda|^2 \right] + \lambda(t - n)c_0
\leq (1 - \lambda(t - n)a_{\mathcal{F}K})(1 - \lambda a_{\mathcal{F}K})\mathbb{E} \left[ |\tilde{\theta}_{n-1}^\lambda|^2 \right] + (1 - \lambda(t - n)a_{\mathcal{F}K})\lambda c_0 + c_0
\leq (1 - \lambda(t - n)a_{\mathcal{F}K})(1 - \lambda a_{\mathcal{F}K})\mathbb{E} \left[ |\tilde{\theta}_{n-1}^\lambda|^2 \right] + \lambda c_0 + c_0
\leq \ldots
\leq (1 - \lambda(t - n)a_{\mathcal{F}K})(1 - \lambda a_{\mathcal{F}K})^n\mathbb{E} \left[ |\theta_0|^2 \right] + c_0(1 + 1/(a_{\mathcal{F}K}))
= (1 - \lambda(t - n)a_{\mathcal{F}K})(1 - \lambda a_{\mathcal{F}K})^n\mathbb{E} \left[ |\theta_0|^2 \right] + \tilde{c}_0,
\]
where \(\tilde{c}_0 := c_0(1 + 1/(a_{\mathcal{F}K}))\).

\textbf{Proof of Lemma 5.1-(ii).} Let \(p \in [2, \infty) \cap \mathbb{N}, 0 < \lambda \leq \lambda_{p, \max}\) with \(\lambda_{p, \max}\) given in \((34), n \in \mathbb{N}_0,\) and \(t \in (n, n + 1].\) Recall the explicit expression of \(\epsilon\)-THEx POULA given in \((37),\) and the definitions of \(\Delta_{n,t}^\lambda, \Xi_{n,t}^\lambda\) given in \((69).\) By using \([8, \text{Lemma A.3}],\) straightforward calculations yield
\[
\mathbb{E} \left[ |\tilde{\theta}_n^p|^2 | \tilde{\theta}_n^\lambda \right] = \mathbb{E} \left[ (\Delta_{n,t}^\lambda)^2 + 2(\Delta_{n,t}^\lambda, \Xi_{n,t}^\lambda) + |\Xi_{n,t}^\lambda|^2 \right] | \tilde{\theta}_n^\lambda
= \mathbb{E} \left[ |\Delta_{n,t}^\lambda|^2 | \tilde{\theta}_n^\lambda \right] + 2p\mathbb{E} \left[ |\Delta_{n,t}^\lambda (2p - 2)(\Delta_{n,t}^\lambda, \Xi_{n,t}^\lambda) | \tilde{\theta}_n^\lambda \right]
+ \mathbb{E} \left[ \sum_{k_1+k_2+k_3=p \backslash \{k_1 \neq p-1 \cap r \neq k_2 \}} \frac{p^1}{k_1!k_2!k_3!} |\Delta_{n,t}^\lambda |^{2k_1}(2(\Delta_{n,t}^\lambda, \Xi_{n,t}^\lambda))^{k_2} |\Xi_{n,t}^\lambda |^{2k_3} \tilde{\theta}_n^\lambda \right]
\leq \mathbb{E} \left[ |\Delta_{n,t}^\lambda |^{2p} | \tilde{\theta}_n^\lambda \right] + 2p\mathbb{E} \left[ |\Delta_{n,t}^\lambda (2p - 2)(\Delta_{n,t}^\lambda, \Xi_{n,t}^\lambda) | \tilde{\theta}_n^\lambda \right]
+ \sum_{k=2}^{2p} \left( \frac{2p}{k} \right) \mathbb{E} \left[ |\Delta_{n,t}^\lambda (2p - 2)(\Delta_{n,t}^\lambda, \Xi_{n,t}^\lambda) | \tilde{\theta}_n^\lambda \right]
= \mathbb{E} \left[ |\Delta_{n,t}^\lambda |^{2p} | \tilde{\theta}_n^\lambda \right] + \sum_{k=2}^{2p} \left( \frac{2p}{k} \right) \mathbb{E} \left[ |\Delta_{n,t}^\lambda (2p - 2)(\Delta_{n,t}^\lambda, \Xi_{n,t}^\lambda) | \tilde{\theta}_n^\lambda \right],
\]
where the last equality holds due to the fact that the second term in \((85)\) is zero. The second term on the RHS of \((86)\) can be further estimated as
\[
\sum_{k=2}^{2p} \left( \frac{2p}{k} \right) \mathbb{E} \left[ |\Delta_{n,t}^\lambda (2p - 2)(\Delta_{n,t}^\lambda, \Xi_{n,t}^\lambda) | \tilde{\theta}_n^\lambda \right]
= \sum_{l=0}^{2p-2} \left( \frac{2p}{l} \right) \mathbb{E} \left[ |\Delta_{n,t}^\lambda |^{2p-2-l}(\Xi_{n,t}^\lambda) | \tilde{\theta}_n^\lambda \right]
= \sum_{l=0}^{2p-2} \frac{2p(2p - 1)}{(l + 2)(l + 1)} \mathbb{E} \left[ |\Delta_{n,t}^\lambda |^{2p-2-l}(\Xi_{n,t}^\lambda) | \tilde{\theta}_n^\lambda \right]
\leq p(2p - 1)\mathbb{E} \left[ (|\Delta_{n,t}^\lambda | + |\Xi_{n,t}^\lambda|) | \tilde{\theta}_n^\lambda \right]
\leq 2^{2p-3} p(2p - 1)\mathbb{E} \left[ |\Delta_{n,t}^\lambda | | \tilde{\theta}_n^\lambda \right] + 2^{2p-3} p(2p - 1)\mathbb{E} \left[ |\Xi_{n,t}^\lambda|^2 \right]
\leq 2^{2p-2} p(2p - 1)\lambda(t - n)d\beta^{-1} \mathbb{E} \left[ |\Delta_{n,t}^\lambda |^{2p-2} | \tilde{\theta}_n^\lambda \right] + 2^{2p-4} (2p - 1)(d\beta^{-1}(\lambda(t - n))^p).
where the second inequality holds due to (68) (with $l \leftarrow 2, z \leftarrow 2p - 2$) and due to the fact that $\Delta_{\lambda,t}^k$ is independent of $\Xi_{\lambda,t}$, and where the last inequality holds due to [44, Theorem 7.1]. Substituting (87) into (86) yields

$$E \left[ |\tilde{\theta}_n^\lambda|^{2p} |\tilde{\theta}_n^\lambda| \right] \leq E \left[ |\Delta_{\lambda,t}^{k+1}|^{2p} |\tilde{\theta}_n^\lambda| \right] + 2^{2p-2} \lambda(t-n)d\beta^{-1} E \left[ |\Delta_{\lambda,t}^{k+1}|^{2p+1} |\tilde{\theta}_n^\lambda| \right]$$

$$+ 2^{2p-4}(2p(2p-1))^{p+1} (d\beta^{-1})^p (t-n)^p.$$

(88)

Then, we proceed with establishing an upper estimate for the first term on the RHS of (88). By using (69), [8, Lemma A.3], and by using the same arguments as in (85), one obtains

$$E \left[ |\Delta_{\lambda,t}^{k+1}|^{2p} |\tilde{\theta}_n^\lambda| \right] = 2 \left[ |\tilde{\theta}_n^\lambda|^{2p} - 2 \lambda(t-n)|\tilde{\theta}_n^\lambda|^{2p-2} E \left[ (\tilde{\theta}_n^\lambda, H_\lambda(\tilde{\theta}_n^\lambda, X_{n+1}))(t-n)^2 \right] \right] |\tilde{\theta}_n^\lambda|$$

$$+ \sum_{k=2}^{2p} \left( \frac{2p}{k} \right) \lambda^k(t-n)^k |\tilde{\theta}_n^\lambda|^{2p-k} E \left[ |H_\lambda(\tilde{\theta}_n^\lambda, X_{n+1})|^k \right] |\tilde{\theta}_n^\lambda|.$$

(89)

One observes that, by Lemma A.1, and by applying (68) (with $l \leftarrow 2, z \leftarrow 2$), the following inequalities hold:

$$|G_\lambda(\tilde{\theta}_n^\lambda, X_{n+1})|^2 \leq 4d\lambda^{-1},$$

$$|F_\lambda(\tilde{\theta}_n^\lambda, X_{n+1})|^2 \leq 2d\lambda^{-1}(1 + |X_{n+1}|)^{2p} K_F^2 + 2\lambda^{-1}(1 + |X_{n+1}|)^2 K_F^2 |\tilde{\theta}_n^\lambda|^2.$$

(90)

For any $k = 2, \ldots, 2p$, by using (6), (68) (with $l \leftarrow 2, z \leftarrow k$), and (90), one obtains that

$$|H_\lambda(\tilde{\theta}_n^\lambda, X_{n+1})|^k \leq 2^{k-1} \left( |G_\lambda(\tilde{\theta}_n^\lambda, X_{n+1})|^2 \right)^{k/2} + 2^{k-1} \left( |F_\lambda(\tilde{\theta}_n^\lambda, X_{n+1})|^2 \right)^{k/2}$$

$$\leq 2^{2k-1} \lambda^{k/2} \lambda^{-k/2} + 2^{2k-2} d^{k/2} \lambda^{-k/2}(1 + |X_{n+1}|)^{2k} K_F^k$$

$$+ 2^{k-2} \lambda^{-k/2}(1 + |X_{n+1}|)^{2k} K_F^k |\tilde{\theta}_n^\lambda|^k,$$

(91)

where the last inequality holds due to $k/2 \geq 1$ and due to (68) (with $l \leftarrow 2, z \leftarrow k/2$). Substituting (72), (91) into (89) yields

$$E \left[ |\Delta_{\lambda,t}^{k+1}|^{2p} |\tilde{\theta}_n^\lambda| \right] \leq |\tilde{\theta}_n^\lambda|^{2p} - 2 \lambda(t-n)|\tilde{\theta}_n^\lambda|^{2p-2} E \left[ (\tilde{\theta}_n^\lambda, H_\lambda(\tilde{\theta}_n^\lambda, X_{n+1}))(t-n)^2 \right]$$

$$+ \sum_{k=2}^{2p} \left( \frac{2p}{k} \right) \lambda^k(t-n)^k |\tilde{\theta}_n^\lambda|^{2p-k} 2 \lambda^{-k/2} d^{k/2} |(1 + |X_0|)^{2k} + K_F^k |\tilde{\theta}_n^\lambda|^k |K_F^k,$$

(92)

where we use the independence of $\tilde{\theta}_n^\lambda$ and $X_{n+1}$. For any $\theta \in \mathbb{R}^d$ and for $\nu = -2, -1, 2r - 2$, one observes that $|\theta|^{2p+\nu} \leq 1 + |\theta|^{2p+2r-1}$, then, by using the same arguments as in (75), one obtains

$$|\theta|^{2p-1} \leq 1 + \frac{2|\theta|^{2p+2r-1}}{1 + \sqrt{\lambda}|\theta|^{2r}}, |\theta|^{2p-2} \leq 2 + \frac{2|\theta|^{2p+2r-1}}{1 + \sqrt{\lambda}|\theta|^{2r}}.$$

(93)
By applying (93) to (92), and by using $|\theta|^{2p-k} \leq 1 + |\theta|^{2p-1}$, for any $\theta \in \mathbb{R}^d$, $2 \leq k \leq 2p$, we have

$$
\mathbb{E} \left[ |\Delta_{n,t}^\lambda|^{2p} \right] \leq \left| \hat{\theta}_n^{[2p]} \right|^{2p} - \frac{2p\lambda(t-n)a_F|\hat{\theta}_n^{[2p]}|^{2r+2p}}{1 + \sqrt{\lambda}|\hat{\theta}_n^{[2]}|^{2r}} \\
+ pd\lambda(t-n)(2 + 4b_F + 2^{2r+2}K_G\mathbb{E}[(1 + |X_0|)^p]) \\
+ pd\lambda(t-n)(2^{2r+3}K_G\mathbb{E}[(1 + |X_0|)^p] + 4b_F + 6)|\hat{\theta}_n|^{2r+2p-1} \\
+ \left(\frac{2p}{p}\right)(2p-1)2^{4p-2}\lambda(t-n)d^p(2 + K_F)^{2p}\mathbb{E}[(1 + |X_0|)^{2p}](1 + |\hat{\theta}_n|^{2p-1}) \\
+ \sum_{k=2}^{2p} \left(\frac{2p}{p}\right) \lambda^{k/2}(t-n)2^{2k-2}K_F^k\mathbb{E}[(1 + |X_0|)^{2}k]||\hat{\theta}_n|^{2p}.
$$

(94)

By using the first inequality in (93), and by using

$$
|\theta|^{2p} = \frac{|\theta|^{2p} + \sqrt{\lambda}|\theta|^{2p+2r}}{1 + \sqrt{\lambda}|\theta|^{2r}} \leq 1 + \frac{|\theta|^{2p+2r-1}}{1 + \sqrt{\lambda}|\theta|^{2r}} + \frac{\sqrt{\lambda}|\theta|^{2p+2r}}{1 + \sqrt{\lambda}|\theta|^{2r}},
$$

for any $\theta \in \mathbb{R}^d$, (94) can be upper bounded as follows:

$$
\mathbb{E} \left[ |\Delta_{n,t}^\lambda|^{2p} \right] \leq \left| \hat{\theta}_n^{[2p]} \right|^{2p} - \frac{2p\lambda(t-n)a_F|\hat{\theta}_n^{[2p]}|^{2r+2p}}{1 + \sqrt{\lambda}|\hat{\theta}_n^{[2]}|^{2r}} \\
+ pd\lambda(t-n)(2 + 4b_F + 2^{2r+2}K_G\mathbb{E}[(1 + |X_0|)^p]) \\
+ pd\lambda(t-n)(2^{2r+3}K_G\mathbb{E}[(1 + |X_0|)^p] + 4b_F + 6)|\hat{\theta}_n|^{2r+2p-1} \\
+ \frac{d^p\lambda(t-n)\left(\frac{2p}{p}\right)(2p-1)2^{4p-2}\lambda(t-n)d^p(2 + K_F)^{2p}\mathbb{E}[(1 + |X_0|)^{2p}]|\hat{\theta}_n|^{2r+2p-1}}{1 + \sqrt{\lambda}|\hat{\theta}_n^{[2]}|^{2r}} \\
+ \frac{\lambda(t-n)\left(\frac{2p}{p}\right)(2p-1)2^{4p-2}\lambda(t-n)d^p(2 + K_F)^{2p}\mathbb{E}[(1 + |X_0|)^{2p}]|\hat{\theta}_n|^{2r+2p-1}}{1 + \sqrt{\lambda}|\hat{\theta}_n^{[2]}|^{2r}} \\
+ \frac{\lambda(t-n)\left(\frac{2p}{p}\right)(2p-1)2^{4p-2}\lambda(t-n)d^p(2 + K_F)^{2p}\mathbb{E}[(1 + |X_0|)^{2p}]|\hat{\theta}_n|^{2r+2p-1}}{1 + \sqrt{\lambda}|\hat{\theta}_n^{[2]}|^{2r}}
$$

(95)

where for any $\theta \in \mathbb{R}^d$,

$$
T_3(\theta) := \frac{a_F|\theta|^{2r}}{1 + \sqrt{\lambda}|\theta|^{2r}} - \frac{pd(2^{2r+3}K_G\mathbb{E}[(1 + |X_0|)^p] + 4b_F + 6)|\theta|^{2r-1}}{1 + \sqrt{\lambda}|\theta|^{2r}} \\
- \frac{d^p\left(\frac{2p}{p}\right)(2p-1)2^{4p}(2 + K_F)^{2p}\mathbb{E}[(1 + |X_0|)^{2p}]|\theta|^{2r-1}}{1 + \sqrt{\lambda}|\theta|^{2r}}
$$

(96)

and

$$
T_4(\theta) := \sum_{k=2}^{2p} \left(\frac{2p}{p}\right) \lambda^{(k-1)/2}2^{2k-2}K_F^k\mathbb{E}[(1 + |X_0|)^{2}k]|\theta|^{2r+2p-1}.
$$
One obtains that

\[ T_3(\theta) = \frac{a_F|\theta|^{2r}}{1 + \sqrt{\lambda}|\theta|^{2r}} - \frac{pd(2^{2r+3}K_G\mathbb{E}[(1 + |X_0|)^p] + 4b_F + 6)|\theta|^{2r-1}}{1 + \sqrt{\lambda}|\theta|^{2r}} \]
\[ - \frac{d^p(\frac{2p}{p}) (2p - 1)2^{4p}(2 + K_F)^{2p}\mathbb{E}[(1 + |X_0|)^{2rp}]|\theta|^{2r-1}}{1 + \sqrt{\lambda}|\theta|^{2r}} \]
\[ \text{for} \ a_F > \frac{a_F|\theta|^{2r}}{2(1 + \sqrt{\lambda}|\theta|^{2r})} \]
\[ \Leftrightarrow |\theta| > \frac{2pd(2^{2r+3}K_G\mathbb{E}[(1 + |X_0|)^p] + 4b_F + 6)}{a_F} \]
\[ + \frac{d^p(\frac{2p}{p}) (2p - 1)2^{4p+1}(2 + K_F)^{2p}\mathbb{E}[(1 + |X_0|)^{2rp}]}{a_F}. \]

Denote by \( M_1(p) := (2pd(2^{2r+3}K_G\mathbb{E}[(1 + |X_0|)^p] + 4b_F + 6) + d^p(\frac{2p}{p}) (2p - 1)2^{4p+1}(2 + K_F)^{2p}\mathbb{E}[(1 + |X_0|)^{2rp}]) / \min \{1, a_F\} \). The above inequality and the fact that \( f(s) := s/(1 + \sqrt{\lambda}s) \) is non-decreasing for any \( s \geq 0 \) imply that, for any \( |\theta| > M_1(p) \),

\[ T_3(\theta) > \frac{a_F|\theta|^{2r}}{2(1 + \sqrt{\lambda}|\theta|^{2r})} \geq \frac{a_F(M_1(p))^{2r}}{2(1 + \sqrt{\lambda}(M_1(p))^{2r})} \geq 2a_F\bar{\kappa}(p), \] (97)

where \( \bar{\kappa}(p) := (M_1(p))^{2r}/(4(1 + (M_1(p))^{2r})) \). Furthermore, one notes that, for any \( \theta \in \mathbb{R}^d \), \( k = 2, \ldots, 2p \),

\[ \frac{a_F|\theta|^{2r+2p}}{1 + \sqrt{\lambda}|\theta|^{2r}} - \binom{2p}{k} \lambda^{(k-1)/2} 2^{2k-2} K_F^k \mathbb{E}[(1 + |X_0|)^{2pk}] |\theta|^{2r+2p} \geq 0 \]
\[ \Leftrightarrow \lambda \leq \lambda_{p,k} := \frac{(a_F/K_F)^{2/(k-1)}}{16K_F^2((2p/k)\mathbb{E}[(1 + |X_0|)^{2pk}])^{2/(k-1)}}. \] (98)

To see that \( \lambda \leq \lambda_{p,max} \leq \lambda_{p,k} \) is indeed satisfied, observes that, for any \( 2 \leq k \leq 2p \),

\[ \left( \binom{2p}{k} \mathbb{E}[(1 + |X_0|)^{2pk}] \right)^{2/(k-1)} = \left( \frac{2p(2p-1)\cdots(2p-k+1)}{k(k-1)\cdots1} \right)^{2/(k-1)} \mathbb{E}[(1 + |X_0|)^{2pk}]^2 \]
\[ \leq \binom{2p}{k}^{2/(k-1)} (2p-1)^2(\mathbb{E}[(1 + |X_0|)^{2rp}]^2) \]
\[ \leq p^2(2p-1)^2(\mathbb{E}[(1 + |X_0|)^{2rp}])^2. \]

By using the above inequality and the definition of \( \lambda_{p,max} \) in (34), it indeed holds that, for any \( k = 2, \ldots, 2p \),

\[ \lambda \leq \lambda_{p,max} \leq \frac{\min\{(a_F/K_F)^{2}, (a_F/K_F)^{2/(2p-1)}\}}{16K_F^2p^2(2p-1)^2(\mathbb{E}[(1 + |X_0|)^{2rp}])^2} \leq \lambda_{p,k}. \] (99)

Thus, by using (98), (99), and the expression of \( T_4 \) in (96), one obtains, for any \( \theta \in \mathbb{R}^d \), that

\[ T_4(\theta) \geq 0. \] (100)

Denote by \( S_{n,M_1(p)} := \{ \omega \in \Omega : |\tilde{\theta}_n^\lambda(\omega)| > M_1(p) \} \). Substituting (97), (100) into (95) yields

\[ \mathbb{E} \left[ |\Delta_{n,t}^\lambda|^{2p} 1_{S_{n,M_1(p)}} \left| \tilde{\theta}_n^\lambda \right|^2 \right] \leq C \left( 1 - 2\lambda(t - n) a_F \bar{\kappa} + \lambda(t - n) c_3(p) 1_{S_{n,M_1(p)}} \right), \] (101)
where \( c_3(p) = \text{pd}\mathbb{E}\left[ (1 + |X_0|)^{2p} \right] (2 + 4b_F + 2^{2r+2}K_G) + \text{pd}^2 \binom{2p}{p} (2p - 1) 2^{4p} (2 + K_F)^{2p}\mathbb{E}\left[ (1 + |X_0|)^{2p} \right]. \)

Similarly, by using (95), (100), one obtains

\[
\mathbb{E}\left[ |\Delta_{n,t}^{\lambda} 2^{p} \mathbb{I}_{S_{n,M_1(p)}} \|^2 \right] \\
\leq (1 - 2\lambda(t-n)a_F \bar{K}(p)) |\bar{\theta}_n^{\lambda}|^{2p} \mathbb{I}_{S_{n,M_1(p)}} + \lambda(t-n)c_3(p) \mathbb{I}_{S_{n,M_1(p)}} + 2\lambda(t-n)a_F \bar{K}(p)(M_1(p))^{2p}\mathbb{I}_{S_{n,M_1(p)}} \\
+ \lambda(t-n)pd(2^{2r+3}K_G\mathbb{E}\left[ (1 + |X_0|)^{2p} \right] + 4b_F + 6)(M_1(p))^{2r+2p-1}\mathbb{I}_{S_{n,M_1(p)}} \\
+ \lambda(t-n)\text{pd}^2 \binom{2p}{p} (2p - 1) 2^{4p} (2 + K_F)^{2p}\mathbb{E}\left[ (1 + |X_0|)^{2p} \right](M_1(p))^{2r+2p-1}\mathbb{I}_{S_{n,M_1(p)}}.
\]

Combining the results in (101) and (102) yields

\[
\mathbb{E}\left[ |\Delta_{n,t}^{\lambda} 2^{p} \mathbb{I}_{S_{n,M_1(p)}} \|^2 |\bar{\theta}_n^{\lambda} \right] = \mathbb{E}\left[ |\Delta_{n,t}^{\lambda} 2^{p} \mathbb{I}_{S_{n,M_1(p)}} \|^2 |\bar{\theta}_n^{\lambda} \right] + \mathbb{E}\left[ |\Delta_{n,t}^{\lambda} 2^{p} \mathbb{I}_{S_{n,M_1(p)}} \|^2 \mathbb{I}_{S_{n,M_1(p)}} \right] \\
\leq (1 - 2\lambda(t-n)a_F \bar{K}(p)) |\bar{\theta}_n^{\lambda}|^{2p} + \lambda(t-n)c_4(p),
\]

where

\[
c_4(p) := c_3(p) + 2a_F \bar{K}(p)(M_1(p))^{2p} \\
+ \text{pd}\mathbb{E}\left[ (1 + |X_0|)^{2p} \right] (2^{2r+3}K_G + 4b_F + 6)(M_1(p))^{2r+2p-1} \\
+ \text{pd}^2 \binom{2p}{p} (2p - 1) 2^{4p} (2 + K_F)^{2p}\mathbb{E}\left[ (1 + |X_0|)^{2p} \right](M_1(p))^{2r+2p-1}.
\]

Define

\[
M_1(1) := 2d(2^{2r+3}K_G\mathbb{E}\left[ (1 + |X_0|)^{2p} \right] + 4b_F + 6)/\min \{1, a_F\} \\
+ 64(2 + K_F)^2\mathbb{E}\left[ (1 + |X_0|)^{2p} \right]/\min \{1, a_F\},
\]

\[
c_4(1) := d\mathbb{E}\left[ (1 + |X_0|)^{2p} \right] (2 + 4b_F + 2^{2r+2}K_G) + 32d(2 + K_F)^2\mathbb{E}\left[ (1 + |X_0|)^{2p} \right] \\
+ 2a_F(M_1(1))^{2r+2} / (4(1 + (M_1(1))^{2r})) \\
+ d\mathbb{E}\left[ (1 + |X_0|)^{2p} \right] (2^{2r+3}K_G + 4b_F + 6)(M_1(1))^{2r+1} \\
+ 32d(2 + K_F)^2\mathbb{E}\left[ (1 + |X_0|)^{2p} \right](M_1(1))^{2r+1}.
\]

By using (82) and the fact that \( 0 < \lambda \leq \lambda_{1,\text{max}} \leq a_F^2/(9\mathbb{E}\left[ (1 + |X_0|)^{2p} \right]^2 K_G^4), \) one obtains

\[
\mathbb{E}\left[ |\Delta_{n,t}^{\lambda} \|^2 \right] |\bar{\theta}_n^{\lambda} \leq |\bar{\theta}_n^{\lambda}|^{2} + \lambda(t-n)c_2 \leq |\bar{\theta}_n^{\lambda}|^{2} + \lambda(t-n)c_4(1),
\]

which, together with (103) implies

\[
\mathbb{E}\left[ |\Delta_{n,t}^{\lambda} 2^{p-1} \|^2 |\bar{\theta}_n^{\lambda} \right] \leq |\bar{\theta}_n^{\lambda}|^{2(p-1)} + \lambda(t-n)c_4(p-1).
\]

By substituting (103), (104) into (88), one obtains

\[
\mathbb{E}\left[ |\bar{\theta}_n^{\lambda}|^{2p} \right] \leq (1 - 2\lambda(t-n)a_F \bar{K}(p)) |\bar{\theta}_n^{\lambda}|^{2p} + \lambda(t-n)c_4(p) \\
+ 2^{2p-2}p(2p - 1) \lambda(t-n)(2^{2p-2} - 1) |\bar{\theta}_n^{\lambda}|^{2(p-1)} \\
+ 2^{2p-4}(2p(2p - 1))^{p+1}(d\beta^{-1}\lambda(t-n))^p.
\]

One observes that for any \( \theta \in \mathbb{R}^d, \)

\[
-\lambda(t-n)a_F \bar{K}(p) |\theta|^{2p} + 2^{2p-2}p(2p - 1) \lambda(t-n)(2^{2p-2} - 1) |\theta|^{2(p-1)} < 0 \\
\leftrightarrow |\theta| > (2^{2p-2}p(2p - 1)d\beta^{-1}/(a_F \bar{K}(p)))^{1/2} := M_2(p).
\]
Let $S_{n,M_2(p)} := \{ \omega \in \Omega : |\tilde{\theta}_n^\omega| > M_2(p) \}$. By using the above inequality, and by using $0 < \lambda \leq \lambda_{p,\text{max}} \leq 1, 0 < t - n \leq 1$, one obtains

$$
\mathbb{E} \left[ |\tilde{\theta}_n^2|^2 I_{S_{n,M_2(p)}} | \tilde{\theta}_n^2 \right] \leq \left( 1 - \lambda(t-n)a_F \bar{\kappa}(p) \right) |\tilde{\theta}_n^2|^2 \mathbb{E} \left[ 1 + |X_0|^2 \right] + \lambda(t-n)c_4(p) I_{S_{n,M_2(p)}}
$$

\begin{equation}
+ \lambda(t-n)2^{2p-2}p(2p-1)I_{S_{n,M_2(p)}} + \lambda(t-n)2^{2p-1}(2(2p-1))^{p+1}d^{-1}\text{P}^2 I_{S_{n,M_2(p)}}.
\end{equation}

In addition, straightforward calculations yield

$$
\mathbb{E} \left[ |\tilde{\theta}_n^2|^2 I_{S_{n,M_2(p)}} | \tilde{\theta}_n^2 \right] \leq \left( 1 - \lambda(t-n)a_F \bar{\kappa}(p) \right) |\tilde{\theta}_n^2|^2 \mathbb{E} \left[ 1 + |X_0|^2 \right] + \lambda(t-n)c_4(p) I_{S_{n,M_2(p)}}
$$

\begin{equation}
+ \lambda(t-n)2^{2p-2}p(2p-1)I_{S_{n,M_2(p)}} + \lambda(t-n)2^{2p-1}(2(2p-1))^{p+1}d^{-1}\text{P}^2 I_{S_{n,M_2(p)}}.
\end{equation}

Combining (105) and (106) yields

$$
\mathbb{E} \left[ |\tilde{\theta}_n^2|^2 | \tilde{\theta}_n^2 \right] \leq (1 - \lambda(t-n)a_F \bar{\kappa}(p)) |\tilde{\theta}_n^2|^2 + \lambda(t-n)c_0(p),
$$

where

\begin{align*}
\bar{\kappa}(p) &:= (M_1(p))^{2r}/(4(1 + (M_1(p))^{2r})), \\
M_1(p) &:= \left( 2pd(2^{2r+3} K_G E \left[ 1 + |X_0|^2 \right] + 4b_F + 6) \\
&\quad + d^p \left( \frac{2p}{p} \right) (2p-1)2^{4p+1}(2 + K_F)^{2p}E \left[ 1 + |X_0|^2 \right] \right) / \min \left\{ 1, a_F, \right\}, \\
c_0(p) &:= c_4(p) + 2^{2p-2}p(2p-1)1/\text{P}^2 + c_4(p-1) + 2^{2p-4}(2p-1)1/\text{P}^2, \\
c_4(p) &:= pdE \left[ 1 + |X_0|^2 \right] (2 + 4b_F + 2^{2r+3} K_G + 2a_F \bar{\kappa}(p)(M_1(p))^{2p} \\
&\quad + pdE \left[ 1 + |X_0|^2 \right] (2^{2r+3} K_G + 4b_F + 6)(M_1(p))^{2r+2p-1} \\
&\quad + d^p \left( \frac{2p}{p} \right) (2p-1)2^{4p+1}(2 + K_F)^{2p}E \left[ 1 + |X_0|^2 \right] (1 + (M_1(p))^{2r+2p-1}) \\
M_2(p) &:= (2^{2p-2}p(2p-1)1/\text{P}^2) / (a_F \bar{\kappa}(p))^{1/2}.
\end{align*}

Finally, by using the same arguments as in (84), and by using $\bar{\kappa}(p) \geq \bar{\kappa}(2)$, one obtains

$$
\mathbb{E} \left[ |\tilde{\theta}_n^2|^p \right] \leq (1 - \lambda(t-n)a_F \bar{\kappa}(2)) (1 - a_F \bar{\kappa}(2))^{p} \mathbb{E} \left[ |\theta_0|^2 \right] + c_0(p) + 1/a_F \bar{\kappa}(2)) \\
\leq (1 - \lambda(t-n)a_F \bar{\kappa}(2)) (1 - a_F \bar{\kappa}(2))^{p} \mathbb{E} \left[ |\theta_0|^2 \right] + c_0(p) + 1/a_F \bar{\kappa}(2))
$$

where $\bar{\kappa}_2 := \min\{\bar{\kappa}(2), \bar{\kappa}(2)\}$, $c_0(p) := \max\{c_0(p), c_0(p)\}$ with $\bar{\kappa}(2), \bar{\kappa}(2), \bar{\kappa}(2), \bar{\kappa}(2)$ given in (108) and (127), respectively.

**Proof of Lemma 5.1-(iii).** Let $p \in [2, \infty) \cap \mathbb{N}, 0 < \lambda \leq \lambda_{\text{max}}$ given in (39), $n \in \mathbb{N}_0$, and $t \in (n, n + 1]$. Since $F(\theta, x) = \hat{F}(\theta)$, for any $\theta \in \mathbb{R}^d, x \in \mathbb{R}^m$, by Remark 4.2, one obtains, for any $\theta \in \mathbb{R}^d$,

$$
\langle \theta, \hat{F}(\theta) \rangle = \langle \theta, \mathbb{E}[F(\theta, X_0)] \rangle \geq a_F |\theta|^{2r+2} - b_F,
$$

where $a_F := a/2$ and $b_F := (a/2 + b)R_F^{2r+2} + dK_F^2E(1 + |X_0|^2) / 2a$ with

$$
R_F := \max\{(4b/a)^{1/(2r-\rho)}, q^{1/(2r)}\}.
$$

Moreover, by using the same arguments as in the proof of Lemma A.1, one obtains, for any $\theta \in \mathbb{R}^d$,

$$
|F_{\lambda}^i(\theta, x)| = \left| \frac{\hat{F}(\theta)}{1 + \sqrt{\lambda}|\theta|^{2\rho}} \right| \leq \lambda^{-1/2}E(1 + |X_0|^2)(K_F + K_F|\theta|^\rho).
$$

In order to obtain the 2p-th moment estimate of e-THO POULA (37) under a relaxed stepsize restriction, we follow the proof of Lemma 5.1-(ii) up to (88), and establish upper bounds for $\mathbb{E} \left[ |\Delta_{n,t}^\lambda|^{2p} \right]$ and
\[
\mathbb{E} \left[ |\Delta_{n,t}^{\lambda}|^{2p-2} \right] \leq \mathbb{E} \left[ (T_6(\bar{\theta}_{n,t}))^{p-1} (T_7(\bar{\theta}_{n,t}, X_{n+1}))^{k} \right] \mathbb{E} \left[ \bar{\theta}_{n,t}^{k} \right]
\]

where, for any \( \theta \in \mathbb{R}^d \),
\[
T_6(\theta) := \frac{a_F |\theta|^{2r+2}}{1 + \sqrt{\lambda} |\theta|^{2r}} - \frac{3\lambda K_F^2 \mathbb{E}[(1 + |X_0|)^{2\rho}] |\theta|^{4r+2}}{(1 + \sqrt{\lambda} |\theta|^{2r})^2}.
\]

One observes that, for any \( \theta \in \mathbb{R}^d \),
\[
\sqrt{\lambda} a_F |\theta|^{4r+2} - 3\lambda K_F^2 \mathbb{E}[(1 + |X_0|)^{2\rho}] |\theta|^{4r+2} \geq 0 \quad \Leftrightarrow \quad \lambda \leq \frac{a_F^2}{9K_F^4 \mathbb{E}[(1 + |X_0|)^{2\rho})^2],
\]

which holds true as \( 0 < \lambda \leq \hat{\lambda}_{\max} \leq a_F^2/(9K_F^4 \mathbb{E}[(1 + |X_0|)^{2\rho})^2] \). Therefore, we have, for every \( \theta \in \mathbb{R}^d \), that
\[
T_6(\theta) = \frac{a_F |\theta|^{2r+2} + \sqrt{\lambda} a_F |\theta|^{4r+2} - 3\lambda K_F^2 \mathbb{E}[(1 + |X_0|)^{2\rho}] |\theta|^{4r+2}}{(1 + \sqrt{\lambda} |\theta|^{2r})^2} \geq 0.
\]

By using (112), (111) becomes
\[
|\Delta_{n,t}^{\lambda}|^2 \leq T_6(\bar{\theta}_n) + T_7(\bar{\theta}_n, X_{n+1}),
\]
where for any \( \theta \in \mathbb{R}^d \),
\[
T_6(\theta) := \left( 1 - \frac{\lambda(t-n)a_F |\theta|^{2r}}{1 + \sqrt{\lambda} |\theta|^{2r}} \right) |\theta|^2,
\]
and for any \( \theta \in \mathbb{R}^d, x \in \mathbb{R}^m \),
\[
T_7(\theta, x) := \lambda(t-n)(1 + |x|)^{2\rho} 2^{2r+1} K_G + \frac{\lambda(t-n)(1 + |x|)^{2\rho}(2^{2r+1} K_G + 2) |\theta|^{2r+1}}{1 + \sqrt{\lambda} |\theta|^{2r}} + \frac{\lambda(t-n)d \mathbb{E}[(1 + |X_0|)^{2\rho}] (8 + 6 K_F + K_F^2) |\theta|^{2r+1}}{1 + \sqrt{\lambda} |\theta|^{2r}} + \frac{\lambda(t-n)d \mathbb{E}[(1 + |X_0|)^{2\rho}] (8 + 6 K_F + K_F^2) |\theta|^{2r+1}}{1 + \sqrt{\lambda} |\theta|^{2r}}.
\]

One notes that, since \( 0 < \lambda \leq \hat{\lambda}_{\max} \leq 1/(a_F^2) \), one has, for any \( \theta \in \mathbb{R}^d \setminus \{0, \ldots, 0 \} \),
\[
0 < 1 - \frac{\lambda(t-n)a_F |\theta|^{2r}}{1 + \sqrt{\lambda} |\theta|^{2r}} < 1.
\]

Therefore, by using (113), further calculations yield
\[
\mathbb{E} \left[ |\Delta_{n,t}^{\lambda}|^{2p} \right] = \sum_{k=0}^{p} \binom{p}{k} \mathbb{E} \left[ (T_6(\bar{\theta}_n))^{p-k} (T_7(\bar{\theta}_n, X_{n+1}))^k \right] \mathbb{E} \left[ \bar{\theta}_{n,t}^k \right]
\]
\[
\leq \left(1 - \frac{\lambda(t - n)aF|\bar{\theta}_n^2|^{2z}}{1 + \sqrt{X}|\bar{\lambda}_n|^{2z}}\right)\left|\bar{\theta}_n\right|^{2+p} + \sum_{k=1}^{p} \left(p \choose k\right) \left|\bar{\theta}_n\right|^{2(p-k)}E \left\{(T_{\gamma}(\bar{\theta}_n, X_{n+1}))^k| \bar{\lambda}_n\right\}
\leq \left(1 - \frac{\lambda(t - n)aF|\bar{\theta}_n^2|^{2z}}{1 + \sqrt{X}|\bar{\lambda}_n|^{2z}}\right)\left|\bar{\theta}_n\right|^{2p} + \sum_{k=1}^{p} \left(p \choose k\right) \left|\bar{\theta}_n\right|^{2(p-k)}k!K_k^G
\]
\[+ \sum_{k=1}^{p} \left(p \choose k\right) 4^{k-1} \lambda^k(t - n)^k k! d_k\mathbb{E}\left[(1 + |X_0|)^{2k}\lambda_k^2(2^{2r+1}K_G + 2)^k|\bar{\lambda}_n|^{2p+2r-k}ight]\left(1 + \sqrt{X}|\bar{\lambda}_n|^{2z}\right)^k
\]
\[+ \sum_{k=1}^{p} \left(p \choose k\right) 4^{k-1} \lambda^k(t - n)^k k! d_k\mathbb{E}\left[(1 + |X_0|)^{2k}\lambda_k^2(2^{2r+1}K_G + 2)^k|\bar{\lambda}_n|^{2p+2r-k}ight]\left(1 + \sqrt{X}|\bar{\lambda}_n|^{2z}\right)^k
\]
where the second inequality holds due to Jensen’s inequality and (68) (with \(l \leftarrow 4, z \leftarrow k\)). For any \(\theta \in \mathbb{R}^d, 1 \leq k \leq p\), it holds that \(|\theta|^{2p-2k} \leq 1 + |\theta|^{2p-1} \) and \(|\theta|^{2p+2r-k-k} \leq 1 + |\theta|^{2p+2r-1} \). By using the aforementioned inequalities together with (93), one obtains
\[
\mathbb{E}\left|\Delta_{n,t}^2|\bar{\theta}_n^2\right|\]
\[\leq \left(1 - \frac{\lambda(t - n)aF|\bar{\theta}_n^2|^{2z}}{1 + \sqrt{X}|\bar{\lambda}_n|^{2z}}\right)\left|\bar{\theta}_n\right|^{2p} + \lambda(t - n)d^p\left(p \choose p/2\right) p_{A^p+1}\mathbb{E}\left[(1 + |X_0|)^{2p}\lambda_k^2(2^{2r+1}K_G + 2b_F + 8 + 8K_F + 6K_F^2)\right]^p
\]
\[+ \lambda(t - n)d^p\left(p \choose p/2\right) p_{A^p+1}\mathbb{E}\left[(1 + |X_0|)^{2p}\lambda_k^2(2^{2r+1}K_G + 2b_F + 8 + 8K_F + 6K_F^2)\right]^p|\bar{\lambda}_n|^{2p+2r-1}
\]
\[+ \lambda(t - n)d^p\left(p \choose p/2\right) p_{A^p+1}\mathbb{E}\left[(1 + |X_0|)^{2p}\lambda_k^2(2^{2r+1}K_G + 10 + 8K_F + 3K_F^2)\right]^p|\bar{\lambda}_n|^{2p+2r-k-1}\left(1 + \sqrt{X}|\bar{\lambda}_n|^{2z}\right)^k
\]
\[= \left(1 - \frac{\lambda(t - n)aF|\bar{\theta}_n^2|^{2z}}{2(1 + \sqrt{X}|\bar{\lambda}_n|^{2z})}\right)|\bar{\theta}_n|^{2p} - \lambda(t - n)T_S(\bar{\theta}_n) + \lambda(t - n)c_5(p),
\]
where
\[c_5(p) := d^p\left(p \choose p/2\right) p_{A^p+1}\mathbb{E}\left[(1 + |X_0|)^{2p}\lambda_k^2(2^{2r+1}K_G + 2b_F + 8 + 8K_F + 6K_F^2)\right]^p
\]
\[+ d^p\left(p \choose p/2\right) p_{A^p+1}\mathbb{E}\left[(1 + |X_0|)^{2p}\lambda_k^2(2^{2r+1}K_G + 10 + 8K_F + 3K_F^2)\right]^p,
\]
and where for any \(\theta \in \mathbb{R}^d\),
\[T_S(\theta) := \frac{a_F|\theta|^{2r+2p}}{2(1 + \sqrt{X}|\bar{\lambda}|^{2z})}\]
\[ - d^p \left( \frac{p}{|p/2|} \right) p^4 p^{p+1} \mathbb{E} \left[ (1 + |X_0|)^{2p} \right] (2^{2p+1} K_G + 2 b_F + 8 + 8 K_F + 6 K_F^2)^p \frac{\lambda^{p+1} |\theta|^{2p+2r}}{1 + \lambda^{|\theta|^{2r}}} \]

\[ - d^p \left( \frac{p}{|p/2|} \right) 4^p \mathbb{E} \left[ (1 + |X_0|)^{2p} \right] (2^{2p+1} K_G + 10 + 8 K_F + 3 K_F^2)^p \sum_{k=1}^{p} \frac{\lambda^k |\theta|^{2p+2r-k}}{1 + \lambda^{|\theta|^{2r}}} \cdot \]

One notes that,

\[ a_F |\theta|^{2r+2p} \frac{4(1 + \sqrt{\lambda}|\theta|^{2r})}{4p(1 + \lambda|\theta|^{2r})^k} \]

\[ - d^p \left( \frac{p}{|p/2|} \right) p^{4p+1} \mathbb{E} \left[ (1 + |X_0|)^{2p} \right] (2^{2p+1} K_G + 2 b_F + 8 + 8 K_F + 6 K_F^2)^p |\theta|^{2p+2r-1} \]

\[ > 0 \quad \text{(115)} \]

\[ \Leftrightarrow |\theta| > d^p \left( \frac{p}{|p/2|} \right) p^{4p+2} \mathbb{E} \left[ (1 + |X_0|)^{2p} \right] (2^{2p+1} K_G + 2 b_F + 8 + 8 K_F + 6 K_F^2)^p / a_F, \]

and moreover, for any \( 1 \leq k \leq p, \)

\[ a_F \lambda^{(k-1)/2} |\theta|^{2r+2p} \frac{4p(1 + \sqrt{\lambda}|\theta|^{2r})^k}{4p(1 + \lambda|\theta|^{2r})^k} \]

\[ - d^p \left( \frac{p}{|p/2|} \right) p^{4p+1} \mathbb{E} \left[ (1 + |X_0|)^{2p} \right] (2^{2p+1} K_G + 10 + 8 K_F + 3 K_F^2)^p |\theta|^{2p+2r-1} \]

\[ > 0 \quad \text{(116)} \]

\[ \Leftrightarrow |\theta| > d^p \left( \frac{p}{|p/2|} \right) p^{4p+1} \mathbb{E} \left[ (1 + |X_0|)^{2p} \right] (2^{2p+1} K_G + 10 + 8 K_F + 3 K_F^2)^p / a_F. \]

Denote by \( M_3(p) := d^p \left( \frac{p}{|p/2|} \right) p^{4p+2} \mathbb{E} \left[ (1 + |X_0|)^{2p} \right] (2^{2p+1} K_G + 2 b_F + 10 + 8 K_F + 6 K_F^2)^p / \min \{1, a_F\}. \)

Then, by using (115) and (116), one obtains, for any \( |\theta| > M_3(p), \) that

\[ T_n(\theta) = \frac{a_F |\theta|^{2r+2p}}{4(1 + \sqrt{\lambda}|\theta|^{2r})} \]

\[ - d^p \left( \frac{p}{|p/2|} \right) p^{4p+1} \mathbb{E} \left[ (1 + |X_0|)^{2p} \right] (2^{2p+1} K_G + 10 + 8 K_F + 3 K_F^2)^p \frac{\lambda^{k-1} |\theta|^{2p+2r-k}}{1 + \lambda^{|\theta|^{2r}}} \]

\[ > \frac{a_F |\theta|^{2r+2p}}{4(1 + \sqrt{\lambda}|\theta|^{2r})} \]

\[ - d^p \left( \frac{p}{|p/2|} \right) p^{4p+1} \mathbb{E} \left[ (1 + |X_0|)^{2p} \right] (2^{2p+1} K_G + 10 + 8 K_F + 3 K_F^2)^p \frac{|\theta|^{2p+2r-k}}{1 + \lambda^{|\theta|^{2r}}} \]

\[ + \sum_{k=2}^{p} \left( \frac{a_F |\theta|^{2r+2p}}{4(1 + \lambda|\theta|^{2r})^k} \right) \]

\[ - d^p \left( \frac{p}{|p/2|} \right) p^{4p+1} \mathbb{E} \left[ (1 + |X_0|)^{2p} \right] (2^{2p+1} K_G + 10 + 8 K_F + 3 K_F^2)^p \frac{\lambda^{k-1} |\theta|^{2p+2r-k}}{1 + \lambda^{|\theta|^{2r}}} \]

\[ > \frac{a_F |\theta|^{2r+2p}}{4(1 + \sqrt{\lambda}|\theta|^{2r})} \]

\[ - d^p \left( \frac{p}{|p/2|} \right) p^{4p+1} \mathbb{E} \left[ (1 + |X_0|)^{2p} \right] (2^{2p+1} K_G + 10 + 8 K_F + 3 K_F^2)^p \frac{|\theta|^{2p+2r-k}}{1 + \lambda^{|\theta|^{2r}}} \]

\[ + \sum_{k=2}^{p} \left( \frac{a_F |\theta|^{2r+2p}}{4(1 + \lambda|\theta|^{2r})^k} \right) \]

\[ - d^p \left( \frac{p}{|p/2|} \right) p^{4p+1} \mathbb{E} \left[ (1 + |X_0|)^{2p} \right] (2^{2p+1} K_G + 10 + 8 K_F + 3 K_F^2)^p \frac{\lambda^{k-1} |\theta|^{2p+2r-k}}{1 + \lambda^{|\theta|^{2r}}} \]

\[ > \frac{a_F |\theta|^{2r+2p}}{4(1 + \sqrt{\lambda}|\theta|^{2r})} \]

\[ - d^p \left( \frac{p}{|p/2|} \right) p^{4p+1} \mathbb{E} \left[ (1 + |X_0|)^{2p} \right] (2^{2p+1} K_G + 10 + 8 K_F + 3 K_F^2)^p \frac{\lambda^{k-1} |\theta|^{2p+2r-k}}{1 + \lambda^{|\theta|^{2r}}} \]

\[ > 0, \quad \text{(117)} \]
where the first inequality holds due to \((1 + a)^{k-1} \geq 1 + a^{k-1}\), for \(a \geq 0, 2 \leq k \leq p\). In addition, by using the fact that \(f(s) := s/(1 + \sqrt{s})\) is non-decreasing for any \(s \geq 0\), we have, for any \(|\theta| > M_3(p)\), that
\[
\frac{a_F |\theta|^{2r}}{2(1 + \sqrt{\lambda} |\theta|^{2r})} \geq \frac{a_F (M_3(p))^{2r}}{2(1 + \sqrt{\lambda} (M_3(p))^{2r})} \geq 2a_F \tilde{k}(p),
\]
where \(\tilde{k}(p) := (M_3(p))^{2r}/(4(1 + (M_3(p))^{2r}))\). Denote by \(S_{n,M_3(p)} := \{\omega \in \Omega : |\tilde{\theta}_n^\omega| > M_3(p)\}\). By using (117) and (118), the RHS of (114) can be upper bounded by
\[
\mathbb{E} \left[ |\Delta_{n,t}^\lambda|^{2p} 1_{S_{n,M_3(p)}} |\tilde{\theta}_n^\lambda| \right] \leq (1 - 2\lambda(t - n)a_F\tilde{k}(p)) |\tilde{\theta}_n^\lambda|^{2p} 1_{S_{n,M_3(p)}} + \lambda(t - n)c_5(p) 1_{S_{n,M_3(p)}}.
\]
Similarly, one obtains
\[
\mathbb{E} \left[ |\Delta_{n,t}^\lambda|^{2p} 1_{\tilde{S}_{n,M_3(p)}} |\tilde{\theta}_n^\lambda| \right] \leq (1 - 2\lambda(t - n)a_F\tilde{k}(p)) |\tilde{\theta}_n^\lambda|^{2p} + \lambda(t - n)c_6(p),
\]
where \(c_6(p) := c_5(p) + 2a_F\tilde{k}(p)(M_3(p))^{2p} + d^p \left( \frac{p}{\rho/2} \right) p^{4p+2}\mathbb{E}[(1 + |X_0|)^{2p}]\). Define
\[
M_3(1) := 64d\mathbb{E}[(1 + |X_0|)^{2p}](2^{r+1}K_G + 2b_F + 8K_F + 6K_F^2)/\min\{1, a_F\},
\]
\[
\tilde{k}(1) := (M_3(1))^{2r}/(4(1 + (M_3(1))^{2r})),
\]
\[
c_5(1) := 16d\mathbb{E}[(1 + |X_0|)^{2p}](2^{r+1}K_G + 2b_F + 8K_F + 6K_F^2)
\]
\[
+ 4d\mathbb{E}[(1 + |X_0|)^{2p}](2^{r+1}K_G + 10 + 8K_F + 3K_F^2),
\]
\[
c_6(1) := c_5(1) + 2a_F\tilde{k}(1)(M_3(1))^{2p} + 64d\mathbb{E}[(1 + |X_0|)^{2p}](2^{r+1}K_G + 2b_F + 10 + 8K_F + 6K_F^2)(M_3(1))^{2r+1}
\]
By using (82), one observes that
\[
\mathbb{E} \left[ |\Delta_{n,t}^\lambda|^{2p} |\tilde{\theta}_n^\lambda| \right] \leq |\tilde{\theta}_n^\lambda|^{2p} + \lambda(t - n)c_2 \leq |\tilde{\theta}_n^\lambda|^{2p} + \lambda(t - n)c_6(1).
\]
Then, by using (121), (122), one obtains the following result:
\[
\mathbb{E} \left[ |\Delta_{n,t}^\lambda|^{2p-2} 1_{S_{n,M_3(p)}} |\tilde{\theta}_n^\lambda| \right] \leq |\tilde{\theta}_n^\lambda|^{2p-2} + \lambda(t - n)c_6(p - 1).
\]
Substituting (121), (123) into (88) yields
\[
\mathbb{E} \left[ \tilde{\theta}_n^\lambda |\tilde{\theta}_n^\lambda| \right] \leq (1 - 2\lambda(t - n)a_F\tilde{k}(p)) |\tilde{\theta}_n^\lambda|^{2p} + \lambda(t - n)c_6(p)
\]
\[
+ 2^{2p-2}p(2p - 1)\lambda(t - n)d\beta^{-1}(|\tilde{\theta}_n^\lambda|^{2p-2} + \lambda(t - n)c_6(p - 1))
\]
\[
+ 2^{2p-4}(2p(2p - 1))^{p+1}d\beta^{-1}\lambda(t - n)^p.
\]
One notes that
\[
-\lambda(t - n)a_F\tilde{k}(p)|\tilde{\theta}_n^\lambda|^{2p} + 2^{2p-2}p(2p - 1)\lambda(t - n)d\beta^{-1}(|\tilde{\theta}_n^\lambda|^{2p-2} < 0
\]
\[
\Leftrightarrow |\theta| > (2^{2p-2}p(2p - 1)d\beta^{-1}/(a_F\tilde{k}(p)))^{1/2}.
\]
Denote by $M_4(p) := (2^{2p-2}p(2p-1)d\beta^{-1}/(a_F\bar{\kappa}(p)))^{1/2}$ and $S_{n,M_4(p)} := \{\omega \in \Omega : |\hat{\theta}_n(\omega)| > M_4(p)\}$. By using (124) and the above inequalities, one obtains

$$
E\left[|\hat{\theta}_n|^{2p} 1_{S_{n,M_4(p)}} | \hat{\theta}_n\right] \leq (1 - \lambda(t-n)a_F\bar{\kappa}(p)) |\hat{\theta}_n|^{2p} 1_{S_{n,M_4(p)}} + \lambda(t-n)c_6(p) 1_{S_{n,M_4(p)}} \\
+ \lambda(t-n)^2 2^{p-2} p(2p-1)d\beta^{-1} c_6(p-1) 1_{S_{n,M_4(p)}} \\
+ \lambda(t-n)^2 2^{p-4} (2p(2p-1))^{p+1}(d\beta^{-1})^p 1_{S_{n,M_4(p)}}. 
$$

(125)

Furthermore, it holds that

$$
E\left[|\hat{\theta}_n|^{2p} 1_{S_{n,M_4(p)}} | \hat{\theta}_n\right] \leq (1 - \lambda(t-n)a_F\bar{\kappa}(p)) |\hat{\theta}_n|^{2p} 1_{S_{n,M_4(p)}} + \lambda(t-n)c_6(p) 1_{S_{n,M_4(p)}} \\
+ \lambda(t-n)^2 2^{p-2} p(2p-1)d\beta^{-1} ((M_4(p))^{2p-2} + c_6(p-1)) 1_{S_{n,M_4(p)}} \\
+ \lambda(t-n)^2 2^{p-4} (2p(2p-1))^{p+1}(d\beta^{-1})^p 1_{S_{n,M_4(p)}}. 
$$

(126)

Combining the two estimates in (125) and (126) yields

$$
E\left[|\hat{\theta}_n|^{2p} 1_{\phi} | \hat{\theta}_n\right] \leq (1 - \lambda(t-n)a_F\bar{\kappa}(p)) |\hat{\theta}_n|^{2p} + \lambda(t-n)c_0(p),
$$

where

$\bar{\kappa}(p) \equiv (M_3(p))^{2p}/4(1 + (M_3(p))^{2p})$, \\

$M_3(p) \equiv dp\left[\frac{p}{p+2}\right] p4^{p+2} E\left[1 + |X_0|^{2p}\right] (2^{2p+1} K_G + 2b_F + 10 + 8K_F + 6K_F^2)^p / \operatorname{min}\{1, a_F\}$, \\

$c_0(p) \equiv c_6(p) + 2^{p-2} p(2p-1)d\beta^{-1} ((M_4(p))^{2p-2} + c_6(p-1)) + 2^{p-4} (2p(2p-1))^{p+1}(d\beta^{-1})^p$, \\

$c_6(p) \equiv dp\left[\frac{p}{p+2}\right] p4^{p+2} E\left[1 + |X_0|^{2p}\right] (2^{2p+1} K_G + 2b_F + 10 + 8K_F + 6K_F^2)^p \\
+ 2a_F\bar{\kappa}(p)(M_3(p))^{2p} + dp\left[\frac{p}{p+2}\right] p4^{p+2} E\left[1 + |X_0|^{2p}\right] (2^{2p+1} K_G + 2b_F + 10 + 8K_F + 6K_F^2)^p \\
\times (2^{2p+1} K_G + 2b_F + 10 + 8K_F + 6K_F^2)^p (M_3(p))^{2p+2p-1}$,

$M_4(p) \equiv (2^{2p-2} p(2p-1)d\beta^{-1}/(a_F\bar{\kappa}(p)))^{1/2}$. 

(127)

Therefore, by using similar arguments as in (84), and by using $\bar{\kappa}(p) \leq \bar{\kappa}(2)$, one obtains

$$
E\left[|\hat{\theta}_n|^{2p}\right] \leq (1 - \lambda(t-n)a_F\bar{\kappa}(2)) (1 - \lambda a_F\bar{\kappa}(2))^{n} E\left[|\theta_0|^{2p}\right] + c_0(p)(1 + (a_F\bar{\kappa}(2))) \\
\leq (1 - \lambda(t-n)a_F\kappa_2^\frac{5}{2} (1 - \lambda a_F\kappa_2^\frac{5}{2})^{n} E\left[|\theta_0|^{2p}\right] + c_0(p)(1 + (a_F\kappa_2^\frac{5}{2})),
$$

where $\kappa_2^5 := \operatorname{min}\{\bar{\kappa}(2), \bar{\kappa}(2)\}$, $c_0^5(p) := \max\{c_0(p), \bar{c}_0(p)\}$ with $\bar{\kappa}(2), \bar{c}_0(p)$ and $\bar{\kappa}(2), \bar{c}_0(p)$ given in (108) and (127), respectively.

**Lemma A.2.** Let Assumptions 1, 2, 3, and 4 hold. Then, for any $0 < \lambda \leq \lambda_{\text{max}}$ with $\lambda_{\text{max}}$ given in (34), $t \geq 0$, one obtains

$$
E\left[|\hat{\theta}_n - \hat{\theta}_n^{(t)}|^{4}\right] \leq \lambda^2 \left(e^{-\lambda a_F\kappa_2^\frac{5}{2}[t]} C_{0,1} \mathbb{E}\left[|\theta_0|^{4(2t+1)}\right] + C_{1,1}\right),
$$

where

$C_{0,1} := 2^{2r+6} d^4 (1 + K_F + K_G)^4 \mathbb{E}\left[(1 + |X_0|)^{4p}\right],$ \\

$C_{1,1} := 2^{2r+6} d^4 (1 + K_F + K_G)^4 \mathbb{E}\left[(1 + |X_0|)^{4p}\right] (1 + \bar{c}_{4t+2}) + 32d(d + 2)b^{-2},$ 

(128)

with $K_H := 2^{2r} K_G + 3\sqrt{2d} K_F$, and $\kappa_2^\frac{5}{2}, \bar{c}_{4t+2}$ given in Lemma 5.1.

**Proof.** The proof follows exactly the same ideas as in the proof of [40, Lemma A.2]. To obtain the explicit constants, recall the expression of $H_\lambda$ given in (6)-(7). By Assumptions 2 and 3, one obtains, for any $\theta \in \mathbb{R}^d, x \in \mathbb{R}^m$,

$$
|H_\lambda(\theta, x)| \leq |G_\lambda(\theta, x)| + |F_\lambda(\theta, x)|
$$
\[ \sum_{i=1}^{d} |G^{(i)}(\theta, x)| + d + |F(\theta, x)| \leq d(1 + K_{G} + K_{F})(1 + |x|)^{\rho}(1 + |\theta|)^{2r+1}. \] (129)

Then, one upper bounds \( H_{\lambda} \) using (129), and replaces [40, Remark 2.2 and Lemma 4.2] with Remark 4.1 and Lemma 5.1, respectively.

**Proof of Lemma 5.6.** The proof follows the exact same ideas as in the proof of [40, Lemma 4.5]. To obtain the explicit constants, let \( 0 < \lambda \leq \lambda_{\text{max}} \) with \( \lambda_{\text{max}} \) given in (34), \( n \in \mathbb{N}_0, t \in (nT, (n+1)T] \). By using the arguments in [40, Eq. (165)] and by Remark 4.1, one observes, for any \( s \in (nT, (n+1)T] \), that

\[ \mathbb{E} \left[ |h(\tilde{\theta}_{s}) - h(\tilde{\theta}(s))|^2 \right] \leq 3^{4r-(1/2)} L_h^2 \left( \mathbb{E} \left[ 1 + |\tilde{\theta}_{s}|^{8r} + |\tilde{\theta}(s)|^{8r} \right] \right)^{1/2} \left( \mathbb{E} \left[ |\tilde{\theta}_{s} - \tilde{\theta}(s)|^4 \right] \right)^{1/2}. \] (130)

Moreover, by (4), (6), (7), and by using \( (a + b)^2 \leq 2a^2 + 2b^2 \) for \( a, b \geq 0 \), one obtains, for any \( s \in (nT, (n+1)T] \),

\[ \begin{align*}
\mathbb{E} \left[ |H(\tilde{\theta}_{[s]}), X_{[s]}| - H(\tilde{\theta}_{[s]}, X_{[s]})|^2 \right] & \leq 2 \sum_{i=1}^{d} \mathbb{E} \left[ G^{(i)}(\tilde{\theta}_{[s]}, X_{[s]}), - G^{(i)}(\tilde{\theta}_{[s]}, X_{[s]}), X_{[s]} \right]^2 + 2 \sum_{i=1}^{d} \mathbb{E} \left[ |F^{(i)}(\tilde{\theta}_{[s]}, X_{[s]}), - F^{(i)}(\tilde{\theta}_{[s]}, X_{[s]}), X_{[s]} \right]^2 \\
& \leq 4 \sum_{i=1}^{d} \mathbb{E} \left[ (1 + \sqrt{X}G^{(i)}(\tilde{\theta}_{[s]}, X_{[s]}))|G^{(i)}(\tilde{\theta}_{[s]}, X_{[s]}), - G^{(i)}(\tilde{\theta}_{[s]}, X_{[s]}), X_{[s]} \right] + 4 \sum_{i=1}^{d} \mathbb{E} \left[ (1 + \sqrt{X}F^{(i)}(\tilde{\theta}_{[s]}, X_{[s]}))|F^{(i)}(\tilde{\theta}_{[s]}, X_{[s]}), - F^{(i)}(\tilde{\theta}_{[s]}, X_{[s]}), X_{[s]} \right] \\
& \leq 4\lambda \sum_{i=1}^{d} \mathbb{E} \left[ |G^{(i)}(\tilde{\theta}_{[s]}, X_{[s]})|^4 + |F^{(i)}(\tilde{\theta}_{[s]}, X_{[s]})|^2 |\tilde{\theta}_{[s]}|^{4r} \right] + 4d\lambda \\
& \leq 4d\lambda (K_G^2 + K_F^2) E \left( (1 + |X_{[s]}|)^{4\rho}(1 + |\tilde{\theta}_{[s]}|)^{8r+4} \right) + 4d\lambda \\
& \leq 2^{8r+5} d\lambda (K_G^2 + K_F^2) E \left( (1 + |X_{[s]}|)^{4\rho}(1 + |\tilde{\theta}_{[s]}|)^{8r+4} \right) + 4d\lambda, \end{align*} \] (131)

where the fourth inequality holds due to Assumptions 2 and 3, and where the last inequality holds due to (68) (with \( l \leftarrow 2, z \leftarrow 8r + 4 \)). Denote by \( \mathcal{H}_t := F_{\infty} \vee G_{[t]} \vee \sigma(\theta_0), t \geq 0 \). Then, following the arguments in [40, Lemma 4.5] up to [40, Eq. (167)], but by using (130) and (131) instead of [40, Eq.
and \([40, \text{Eq. (166)}]\), one obtains that

\[
\mathbb{E} \left[ |\tilde{\zeta}_t|_{\lambda n} - \tilde{\theta}_t^\lambda |^2 \right]
\leq 4\lambda L_R \int_{t}^{T} \mathbb{E} \left[ |\tilde{\zeta}_s|_{\lambda n} - \tilde{\theta}_s^\lambda |^2 \right] \, ds + 4d\lambda L_R^{-1}
\]
\[
+ 3^{4r-1(1/2)} \lambda^2 L_R^2 \int_{nT}^{t} \left( \mathbb{E} \left[ 1 + |\tilde{\theta}_s|^{8r} + |\tilde{\theta}_s^\lambda|^{8r} \right] \right)^{1/2} \left( \mathbb{E} \left[ |\tilde{\theta}_s^\lambda - \tilde{\theta}_s|^{4} \right] \right)^{1/2} \, ds
\]
\[
+ 2^{8r+5} d\lambda^2 (K_G^2 + K_F^2) L_R^{-1} \int_{nT}^{t} E \left[ (1 + |X_{[s]|})^{4\rho}(1 + |\tilde{\theta}_{[s]}|)^{8r+4} \right] \, ds
\]
\[
- 2\lambda \int_{nT}^{t} \mathbb{E} \left[ \left\langle \tilde{\zeta}_{s,n} - \tilde{\theta}_{s}^\lambda, h(\tilde{\theta}_{[s]}^\lambda, X_{[s]}) \right| \mathcal{H}_s \right] \right) \, ds
\]
\[
- 2\lambda^2 \int_{nT}^{t} \mathbb{E} \left[ \left\langle \int_{[s]}^{s} H(\tilde{\theta}_{[r]}, X_{[r]}) \, dr, h(\tilde{\theta}_{[s]}^\lambda, X_{[s]}) \right| \mathcal{H}_s \right] \right) \, ds
\]
\[
+ 2\lambda \sqrt{2\lambda \beta} \int_{nT}^{t} \mathbb{E} \left[ \left\langle \int_{[s]}^{s} dB_r, h(\tilde{\theta}_{[s]}^\lambda, X_{[s]}) \right| \mathcal{H}_s \right] \right) \, ds.
\]

By Remark 4.1 and (129), one obtains the following estimate for the sixth term on the RHS of (132):

\[
- 2\lambda^2 \int_{nT}^{t} \mathbb{E} \left[ \left\langle \int_{[s]}^{s} H(\tilde{\theta}_{[r]}^\lambda, X_{[r]}) \, dr, h(\tilde{\theta}_{[s]}^\lambda, X_{[s]}) - H(\tilde{\theta}_{[s]}^\lambda, X_{[s]}) \right| \mathcal{H}_s \right] \right) \, ds
\]
\[
\leq \lambda^2 \int_{nT}^{t} \mathbb{E} \left[ |H(\tilde{\theta}_{[s]}^\lambda, X_{[s]})|^2 \right] \, ds + \lambda^2 \int_{nT}^{t} \mathbb{E} \left[ |h(\tilde{\theta}_{[s]}^\lambda) - H(\tilde{\theta}_{[s]}^\lambda, X_{[s]})|^2 \right] \, ds
\]
\[
\leq \lambda^2 \int_{nT}^{t} d^2(1 + K_G + K_F)^2 \mathbb{E} \left[ (1 + |X_{[s]|})^{4\rho}(1 + |\tilde{\theta}_{[s]}^\lambda|)^{8r+2} \right] \, ds
\]
\[
+ 2\lambda^2 \int_{nT}^{t} \mathbb{E} \left[ |h(\tilde{\theta}_{[s]}^\lambda)|^2 \right] \, ds + 2\lambda^2 \int_{nT}^{t} \mathbb{E} \left[ |H(\tilde{\theta}_{[s]}^\lambda, X_{[s]})|^2 \right] \, ds
\]
\[
\leq d^2(1 + K_G + K_F)^2 \lambda^2 \int_{nT}^{t} \mathbb{E} \left[ (1 + |X_{[s]|})^{4\rho}(1 + |\tilde{\theta}_{[s]}^\lambda|)^{8r+2} \right] \, ds
\]
\[
+ 4L_h^2 \lambda^2 \int_{nT}^{t} \mathbb{E} \left[ (1 + |\tilde{\theta}_{[s]}^\lambda|)^{4r+2} \right] \, ds + 4\lambda |h(0)|^2
\]
\[
+ 2K_h^2 \lambda^2 \int_{nT}^{t} \mathbb{E} \left[ (1 + |X_{[s]}|)^{4\rho}(1 + |\tilde{\theta}_{[s]}^\lambda|)^{4r+2} \right] \, ds
\]
\[
\leq 2^{8r+3} \left( d^2(1 + K_G + K_F)^2 + 4L_h^2 + 2K_h^2 \right) \lambda^2 \int_{nT}^{t} \mathbb{E} \left[ (1 + |X_{[s]}|)^{4\rho}(1 + |\tilde{\theta}_{[s]}^\lambda|)^{8r+4} \right] \, ds
\]
\[
+ 4\lambda |h(0)|^2.
\]

By Lemma A.2, (133), the fact that the fifth and seventh term of the RHS of (132) are zero, and that \(X_{[s]}\) and \(\tilde{\theta}_{[s]}^\lambda\) are independent for any \(s \geq 0\), one obtains

\[
\mathbb{E} \left[ |\tilde{\zeta}_t|_{\lambda n} - \tilde{\theta}_t^\lambda |^2 \right]
\leq 4\lambda L_R \int_{nT}^{t} \mathbb{E} \left[ |\tilde{\zeta}_s|_{\lambda n} - \tilde{\theta}_s^\lambda |^2 \right] \, ds + 4d\lambda L_R^{-1} + 4\lambda |h(0)|^2
\]
\[
+ 3^{4r-1(1/2)} \lambda^2 L_R^2 \int_{nT}^{t} \left( \mathbb{E} \left[ 1 + |\tilde{\theta}_s|^{8r} + |\tilde{\theta}_s^\lambda|^{8r} \right] \right)^{1/2} \left( \mathbb{E} \left[ |\tilde{\theta}_s^\lambda - \tilde{\theta}_s|^{4} \right] \right)^{1/2} \, ds
\]
\[
+ 2^{8r+5} d\lambda^2 (K_G^2 + K_F^2) L_R^{-1} \int_{nT}^{t} E \left[ (1 + |X_0|)^{4\rho} \right] E \left[ (1 + |\tilde{\theta}_{[s]}^\lambda|)^{8r+4} \right] \, ds
\]
\[
+ 2^{8r+3} \left( d^2(1 + K_G + K_F)^2 + 4L_h^2 + 2K_h^2 \right) \lambda^2 \int_{nT}^{t} \mathbb{E} \left[ (1 + |X_0|)^{2\rho} \right] \mathbb{E} \left[ (1 + |\tilde{\theta}_{[s]}^\lambda|)^{8r+4} \right] \, ds.
This implies, by using Lemma 5.1 and by using $1 - \nu \leq e^{-\nu}$ for any $\nu \in \mathbb{R}$, that

$$
\mathbb{E} \left[ |\tilde{\zeta}_{t}^{\lambda,n} - \tilde{\theta}_{t}^{\lambda}|^2 \right] \leq 4\lambda L_{R} \int_{0}^{t} \mathbb{E} \left[ |\tilde{\zeta}_{s}^{\lambda,n} - \tilde{\theta}_{s}^{\lambda}|^2 \right] \, ds + 4d\lambda L_{R}^{-1} + 4\lambda |h(0)|^2 \\
+ 3^{4r - (1/2)} \lambda^2 L_{R}^2 L_{h}^{-1} \int_{0}^{t} \left( 1 + 2e^{-\lambda_{FR}\kappa_{2}^{4}[s]} \mathbb{E}[|\theta_{0}|^{8r}] + \lambda_{4r} \right)^{1/2} \\
\times \left( e^{-\lambda_{FR}\kappa_{2}^{4}[s]} \tilde{C}_{0,1} \mathbb{E} \left[ |\theta_{0}|^{4(2r+1)} \right] + \tilde{C}_{1,1} \right)^{1/2} \, ds \\
+ \lambda^2 (2^{8r+5} d (K_{G}^4 + K_{F}^2) L_{R}^{-1} + 2^{8r+3} \left( d^2 (1 + K_{G} + K_{F})^2 + 4L_{h}^2 + 2K_{H}^2 \right)) \\
\times \mathbb{E} \left[ (1 + |X_{0}|)^{4p} \right] \int_{0}^{t} \left( 1 + e^{-\lambda_{FR}\kappa_{2}^{4}[s]} \mathbb{E}[|\theta_{0}|^{8r+4}] + \hat{\nu}_{4r+2} \right) \, ds.
$$

By using $|s| \geq nT$ and $1/2 \leq \Lambda T \leq 1$, the above inequality becomes

$$
\mathbb{E} \left[ |\tilde{\zeta}_{t}^{\lambda,n} - \tilde{\theta}_{t}^{\lambda}|^2 \right] \leq 4\lambda L_{R} \int_{0}^{t} \mathbb{E} \left[ |\tilde{\zeta}_{s}^{\lambda,n} - \tilde{\theta}_{s}^{\lambda}|^2 \right] \, ds + 4d\lambda L_{R}^{-1} + 4\lambda |h(0)|^2 \\
+ 3^{4r - (1/2)} \lambda^2 L_{R}^2 L_{h}^{-1} \left( e^{-n\lambda_{FR}\kappa_{2}^{4}/2} \tilde{C}_{0,1} \mathbb{E} \left[ V_{4(2r+1)}(\theta_{0}) \right] + \tilde{C}_{1,1} + \hat{\nu}_{4r+2} \right) \\
+ \lambda (2^{8r+5} d (K_{G}^4 + K_{F}^2) L_{R}^{-1} + 2^{8r+3} \left( d^2 (1 + K_{G} + K_{F})^2 + 4L_{h}^2 + 2K_{H}^2 \right)) \\
\times \mathbb{E} \left[ (1 + |X_{0}|)^{4p} \right] \left( 1 + e^{-n\lambda_{FR}\kappa_{2}^{4}/2} \mathbb{E}[|\theta_{0}|^{8r+4}] + \hat{\nu}_{4r+2} \right) \\
\leq 4\lambda L_{R} \int_{0}^{t} \mathbb{E} \left[ |\tilde{\zeta}_{s}^{\lambda,n} - \tilde{\theta}_{s}^{\lambda}|^2 \right] \, ds + e^{-4LR\lambda} \left( e^{-n\lambda_{FR}\kappa_{2}^{4}/2} \tilde{C}_{0} \mathbb{E} \left[ V_{4(2r+1)}(\theta_{0}) \right] + \tilde{C}_{1} \right),
$$

where

$$
\kappa_{2}^{4} := \min \{ \bar{\kappa}(2), \tilde{\kappa}(2) \}, \\
\tilde{C}_{0} := e^{4LR} (2^{8r+5} d (K_{G}^4 + K_{F}^2) L_{R}^{-1} + 2^{8r+3} \left( d^2 (1 + K_{G} + K_{F})^2 + 4L_{h}^2 + 2K_{H}^2 \right)) \mathbb{E} \left[ (1 + |X_{0}|)^{4p} \right] \\
+ e^{4LR} 3^{4r - (1/2)} L_{h}^2 L_{R}^{-1} \tilde{C}_{0,1}, \\
\tilde{C}_{1} := e^{4LR} (2^{8r+5} d (K_{G}^4 + K_{F}^2) L_{R}^{-1} + 2^{8r+3} \left( d^2 (1 + K_{G} + K_{F})^2 + 4L_{h}^2 + 2K_{H}^2 \right)) \mathbb{E} \left[ (1 + |X_{0}|)^{4p} \right] \\
\times \left( \hat{\nu}_{4r+2} + 1 \right) + e^{4LR} 3^{4r - (1/2)} L_{h}^2 L_{R}^{-1} \left( \tilde{C}_{1,1} + 2\hat{\nu}_{4r} + 1 \right) + e^{4LR} (4dL_{R}^{-1} + 4|h(0)|^2),
$$

(134)

with $\tilde{C}_{0,1}, \tilde{C}_{1,1}$ given in (128), $\bar{\kappa}(2), \tilde{\kappa}(2), \hat{\nu}_{4r}, \hat{\nu}_{4r+2}$ given in Lemma 5.1. Finally, the desired result can be obtained by applying Grönwall’s lemma, which implies that

$$
\mathbb{E} \left[ |\tilde{\zeta}_{t}^{\lambda,n} - \tilde{\theta}_{t}^{\lambda}|^2 \right] \leq \lambda \left( e^{-n\lambda_{FR}\kappa_{2}^{4}/2} \tilde{C}_{0} \mathbb{E} \left[ V_{4(2r+1)}(\theta_{0}) \right] + \tilde{C}_{1} \right).
$$

\[\Box\]
